MILLFORD
SIDE CARS
QUALITY & COMFORT
Mills Fullford Ltd. COVENTRY.
The Original Side Car Makers

MONTGOMERY
SIDECAR

Note the enthusiasm of Montgomery Owners when they talk of "my side car." It is not "swank" but purely natural pride of possession. You would be just the same, because "Montgomerys" are all that a sidecar should be.—**Cosy, Strong, Easy-running, Safe,** and —last but not least— **Inexpensive.**

W. MONTGOMERY & CO. - - Coventry.

BAT MOTOR MFG. CO., PENGE, LONDON, S.E.

Douglas
Defied Tradition

Douglas determined to produce a new and more efficient machine than had been produced before. The result of his determination to excel was the famous little Opposed Twin engine — the engine which has made the Douglas the most popular and successful machine in the world. Do you ride a Douglas?

DOUGLAS BROTHERS,
Kingswood - BRISTOL.

WOLF MOTORS

SPECIAL NOTICE.

The Ministry of Munitions has given us permit to supply any motors, erected or assembled up to the 15th February, 1917. If Agents, therefore, are desirous of securing motors which we have coming through the works they could be delivered before that date; after that date we expect no more motors can be supplied for the English market
THE WILLEBUNA ENGINEERING CO., LTD., WOLVERHAMPTON.

Volex
MOTOR CYCLE LIGHTING.

"VOLEX" DRY BATTERY MOTOR CYCLE HEAD LAMP OUTFIT.

Also supplied in Sidecar Outfit at same price.

Includes "Volex" Giant Dry Battery, Conducting Cord, Switch, and Penetra Motor Cycle Head or Sidecar Lamp, with Bulbs.
Price 32/6 complete outfit.
The battery can be fitted in Sidecar Bottom or carried in Satchel which can be attached to the frame or Motor Cycle. The Dry Battery will give about 80 hours' light, and will hold up in stock for over 12 months.
Spare "Volex" Giant Battery, 6/6.

THE "VOLEX" GIANT DRY BATTERIES.

For Motor Cycle and Sidecar Lighting and Ignitioo Starting they are excellent, and have no superior. "Volex" Batteries are recommended for export.
4 volts, size 6½×3in. square, 6/6 each. 6 volts, size 6½×4×3in. 8/6 each.

THE "VOLEX" AERO DRY BATTERY. British Made.

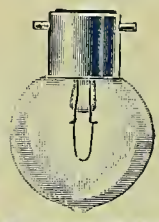
A very convenient size for many purposes, such as Motor Cycles, Cycle Caps, etc. Suitable for ignition, lighting, electric horn operation. Holds up in stock for years.

4 volts, size 6½×4½×2½in. .. Price 8/-.
6 volts, size 6½×6 ×2½in .. Price 11/-.

THE "VOLEX" EMPERAL BATTERY. British Made.

Of particularly heavy capacity, recommended for Motor Car, Boat, or Engine Ignition; for lighting, actuating horn, etc. Recommended for export, and in conjunction with our "Volex" Special Metal Filament Bulbs about 150 to 200 hours' light is obtainable.

4 volts, size 6½×7½×2½in. .. Price 10/6.
6 volts, size 6½×5 ×5in. .. Price 14/6.



THE "VOLEX" Special Metal Filament Bulb

For use with our "Volex" Dry Batteries, ensuring maximum burning hours. 4 and 6 volts, min screw cap. 1/- each. 4 and 6 volts, small B cap. 1/6 each.

"VOLTALITE."

Self-Generating Electric Motor Cycle LAMP. British Made. The FIRST Cost the ONLY Cost. The lamp which produces by the movement of the machine an inexhaustible supply of electric light to illuminate brilliantly the head lamp at no cost whatever. Fitted with Hoffmann Ball Bearings. Complete with head lamp and metal filament bulb, ready for use. £4/4. Post free.

Grams—"Multum, Manchester."
Established 1892.

BLUEMEL'S

SPARKING PLUGS.

Pressure of Government work prevents production of Bluemel Plugs at normal rate. It is well to know, however, all about the Plug which performs its function most faithfully and efficiently. Therefore — send for the Bluemel Booklet which gives the reason why Bluemel's Plugs and other Accessories are so esteemed by motor cyclists.

The Manufacture of Motor Cycles.

SEVERAL motor cycle manufacturers not engaged upon war work have been notified by the authorities that the production of motor cycles must cease on February 15th next. This is serious for those firms who, after vain attempts to obtain war work, have specialised on Overseas trade in response to Government exhortations. The Motor Cycle Manufacturers' Union met last week to discuss the preservation of the motor cycle industry, and a deputation was appointed to wait upon Mr. Neville Chamberlain, the new Director General of National Service, with regard to the situation created.

The volume of our export trade in motor cycles does not seem to be generally appreciated by people outside the trade. Some glibly talk of stopping the production of motor cycles, since they are not of national necessity, but if those critics were to pause for an instant and examine the position, they would see that the British motor cycle industry is one of our national assets, approximately a million pounds worth of motor cycles being exported every year. Moreover, the products of British manufacturers predominate in many countries abroad, and this position has only been obtained after much spade work. To negative all this uphill work by stopping the production of motor cycles for export would mean that manufacturers would have to commence operations all over again, and in many cases would never be able to regain the position they once held. Not a man in the trade fails to realise, however, that the successful prosecution of the war is the first consideration, but is the supply of munitions still so inadequate that industries should be completely wiped out? As the position stands at present there is a million pound British trade in jeopardy—a trade, too, which showed every promise of rapid expansion as time went on. Again, it cannot be urged that the industry has not proved its worth in this great war, for it has rendered of its best in men, machinery, and money right from the commencement. Not only is the army able to obtain as many motor cycles as it wants from home sources, but the requirements of our Allies have been satisfied. Expansion of trade is impossible, but an important industry already considerably affected by war demands should be allowed, if the conditions at all permit, to retain its present slender connections with trade channels in our Colonies and Overseas Dominions and neutral countries.

Overhead Valves.

FOR maximum efficiency there is nothing to equal the overhead valve. This type of valve would figure much more frequently on touring machines were it not for the ever-present possibility of a valve head snapping and falling on to the piston with disastrous results. At any rate such is the prevailing opinion which has existed since the earliest days of motor cycles, when overhead valve breakages were more frequent than they are now. Latterly, however, with improved methods of design and a closer study of metallurgy, we have valves of practically unbreakable material, and engines of such superlative efficiency that valve breakages are becoming few and far between. This happy change of conditions, therefore, may reasonably cause designers to pause and consider whether the bias against overhead valves, which has been prevalent hitherto—and not without justification—may gradually disappear. As we have said, the overhead valve arrangement renders possible an engine design of the highest efficiency by reason of the fact that heat-retaining valve caps are dispensed with, and a simple spherical combustion chamber without ports or passages is obtained. That many of the difficulties at first found inseparable from this type of engine are now removed is proved by the marvellous reliability of modern aero engines.

An index to the advertisements in this issue will be found on the page facing the back cover.

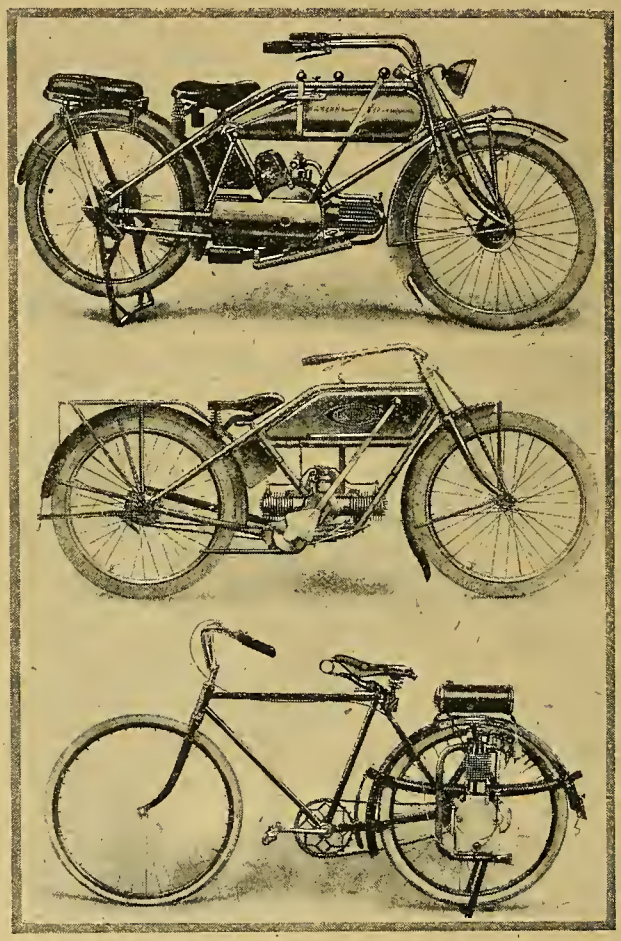
NEW AMERICAN DESIGNS.

A TRIO OF MOTOR CYCLES POSSESSING UNUSUAL FEATURES.

IT is not surprising to find that, the Indian Co. having started the ball rolling by introducing its new flat twin, other American manufacturers are coming forward with similar designs. At the time we described the Indian twin we expressed the opinion that more would follow. In the December issue of our American contemporary, *Motor Cycling and Bicycling*, we find descriptions of two more flat twins, which will make their appearance on the market about March, 1917. One will be known as "The Century" and the other as "The Bailey Flyer." Both machines possess one or two original features, and a few details as regards their construction may be of interest to our readers. The more striking design of the two is perhaps the Bailey, as among other novelties it is provided with shaft transmission—a type of transmission to which the even running of the flat twin lends itself.

The frame design is quite novel. The crank case forms the connection for the frame, as in many of our 3½ h.p.'s, thus allowing the front cylinder to protrude. This design enables a short wheelbase to be obtained, but the front cylinder appears to be in a somewhat exposed position.

The engine is quite a large one, viz., 84.5 mm. × 88.9 mm. = 920 c.c., and is said to develop between 16 and 20 h.p. On the top of the crank case the magneto and carburetter are mounted, and the three-speed gear occupies a position on the side of the engine, the drive being direct to the rear wheel by shaft and bevel gearing. The engine is started by means of a long hand lever at the side of the tank. The Century flat twin is very similar to the Bailey in appearance, but is a lightweight, scaling 130 lb. In this instance the transmission is by chain, while the magneto is incorporated in the flywheel. In this design also the engine starter is in the form of a long hand lever. The frame is divided in order to accommodate the front cylinder of the engine. The gear box occupies the ordinary countershaft position, the drive from the engine being enclosed.



(1) The 920 c.c. flat twin Bailey Flyer. Features are the shaft drive and novel frame construction.

(2) Century flat twin lightweight. The magneto is incorporated in the flywheel.

(3) The new Markel motor wheel. A company has been formed in the U.S.A. with a capital of £40,000 to manufacture this attachment.

A New Motor Attachment.

Another new American novelty described in the same issue is a bicycle motor attachment, a form of motor becoming widely popular in the States at the present time. This attachment is somewhat similar to the well-known Wall Auto-wheel, but is so arranged that, instead of simply attaching it to the side of the bicycle, it actually takes the place of the bicycle rear wheel. The motor is built into an auxiliary frame, so that the driving wheel takes all strains, and does not throw any weight on the bicycle. An ingenious springing device is fitted to take up road and driving shocks. It is stated that the power unit can be substituted for the rear wheel of a pedal cycle in half an hour.

THE NEW LIGHTING RULES NOW IN FORCE.

PART I. of the new Lighting Order of October 22nd came into force last Monday. The regulation referred to specifies that all vehicles, except bicycles, pedal-propelled tricycles, and hand-carts, must henceforward carry two white forward lights and a red rear light. Sidecars and three-wheeled vehicles will, of course, exhibit two forward lights *showing the width of the vehicle* and one rear light, while motor bicycles will meet the requirements of the law by the use of one head lamp properly screened and a red lamp in the rear. An electric lamp must not exceed six inches in the diameter of its lens or glass, and must not be more than twelve candle-power. In the case of acetylene lamps the size limit is identical, and the consumption must not exceed fourteen litres per hour. All lamps but those having no lens fronts and burning oil or paraffin must be screened with tissue paper.

Occasional Comments by "Ixion"

American Factories in England.

IT is already clear that the American trade expects (*a*) a temporary continuance of prohibition after the war, followed by (*b*) protective tariffs; and that the usual retort to such trading methods, *i.e.*, the establishment of new factories inside the prohibition or tariff wall, is to be adopted. This fact settles the question of "quantity" production in this country. Scientific repetition work is undoubtedly going to be applied to the production of motor cycles and motor cars in England, and a new factor of far reaching influence will appear in our industry. It is too early to prophesy with any pretence of accuracy as to what its exact effects will be. Suppose, for example, that a Hendee factory is erected in Great Britain or Ireland (if Mr. Wells will allow me to use his firm as a purely imaginary illustration). It does not follow that British-built 7 h.p. Indians will sell here for £55, which is their market price in the States. That figure depends on four main factors, presumably: the size of the output; the cost of labour; the cost of material; and local charges, such as rent and rates. If the Hendee Co. erected a factory here to dodge, let us say, a post-war import tariff of 33%, it would pay them to do so if the four factors named above kept the price of British-built Indians up to the pre-war figure for imported Indians. Nevertheless, any immigrant American firm is likely to sacrifice an immediate increase in profits to the chance of a tremendous increase in sales, leading ultimately to far bigger profits. In other words, it is on the cards that our best single-cylinders may soon after the war have to compete with the best American twins, and that at an appreciable disadvantage in price. For solo work our riders may mostly prefer the British single to the American twin, as has always been the case; but sidecar work is another pair of shoes altogether.

What about Competitions?

WE must further remember that competitions constitute a form of advertisement which has always had a great influence on our public; and that American machines have sold with comparatively little recourse to competition successes in England. I do not think, for example, that either the Harley-Davidson or the Henderson has ever scored in serious competition over here, or even competed. But the Americans are splendid hands at competition work. In the past, with the single exception of the Indian, they have given our competitions rather a wide berth. But they will all but swamp our competitions if they establish factories over here. They will have the men and other facilities ready to hand, in the way that a small London importing depot could never have. Their increased sales, aided by their familiar business methods, will supply them with large bands of crack sporting amateurs. Our old established factories will have to revise their entire programmes pretty radically to meet all these threats. I am by no means pleading for the adoption of Yankee methods by our trade. Our trade can make, and will continue to make, better machines than America has ever made yet. I suppose the simple fact is that we shall have to effect a certain compromise between our old ideal of "quality" production and the typical Yankee notion of "quantity" production; and that the home and the overseas trade will profit accordingly. But if too large a percentage of our firms stumble blindfold into the rather thorny thicket that lies ahead, they will meet rough times, and will emerge singing Kipling's Boer War ditty:

"We have had no end of a lesson;
It has done us no end of good."

Leaky Petrol Taps.

THE "petroil" system of lubrication attracts much adverse criticism, but it possesses one undeniable advantage in that its greenery-yallery stains infallibly draw an owner's attention to any petrol leaks. I was denouncing the modern petrol tap in rather disgruntled terms the other day, when a friend retorted that petrol taps had leaked as a class since the beginning of time, but that nobody knew it until petroil lubrication coloured the leaks and made them visible. I think I shall take to dissolving a small packet of aniline dyes in my petrol in future whenever it is used on machines undisfigured by the petroil system. Anyhow, the petrol taps of my last three new machines have all leaked sadly, and until the other day I was unaware of a real cure. Grinding them does not seem to make any difference. In one case I found that the leak was not really along the plug of the tap, but was located at the joint between the tap and the tank, and a new lead washer, plentifully besmeared with soap, effected a remedy. In the other two cases a cure—which may, or may not, prove permanent—was obtained by using a new "petrol stop" outfit made by the Chemico people. It is a formidable looking apparatus, really intended for tank leaks; but, mercifully, the modern tank does not leak unless you sideslip and jab one grip of a racing bar through the side panel. The aforesaid outfit consists of paste for caulking any petrol leak; tin angle plates for fitting over the paste, surgical bandage for lashing the plates in position, and shellac varnish for anointing the outside of the bandage, and so keeping the paste dry. Well, I removed the plug of the leaky taps, pushed a dobbet of paste into the taper end of the barrel just beyond the fairway used by the spirit, jammed the plug back, lashed the whole with the bandage, and anointed it with shellac. I cannot now shut the tap, but at any rate it does not leak. Till I strike a new and better make of petrol tap, I must adopt this untidy procedure. The Chemico dope appears to be petrol proof and adheres to the faulty place much better than yellow soap, which has previously been my sole specific for such jobs.

Road Test of a Scott Sociable

Over Yorkshire Hills & Dales in Drenching Rain

IN our issues of July 27th and August 3rd we gave the first full technical description of the Scott three-wheeled sociable, and we have now been privileged to make a practical and thorough road test of this machine, which is of interest not only on account of its ingenuity and originality of conception, but because it may be regarded as a scientific and engineering attempt to bridge the gap between the motor cycle and the light car. The aim of the inventor has been to retain the few but undeniable advantages of the sidecar outfit, while giving car comfort, protection, and rigidity.

The price of the ultimate machine cannot, as yet, be decided, and we can only say that the cost of manufacture compares favourably with that of machines sold in pre-war days at £100.

In testing this machine the following questions were borne in mind as of foremost importance: What are the distinct advantages of the sociable as compared with the luxurious sidecar outfit? Will the motor cyclist, in search of comfort and luxury, accept the Scott Sociable as a convenient stepping-stone between motor cycle and car? To what extent will the new vehicle appeal to those who demand something more on car than on motor cycle lines? Our candid opinion as to the behaviour and running of the machine will prove the easiest and, perhaps, the most convincing way of answering these questions.

Surprising Mobility.

On emerging from the works, Mr. Scott informed us that the engine required warming up before taking the road, and this process was carried out in the restricted area of the factory yard. The machine was run on middle gear at a brisk 10 m.p.h.; figure "eights" and narrow circles were cut, and the yard being at a decided slant, we experienced some qualms as to the likelihood of the sidecar wheel lifting. Nothing of the kind happened, however, and our tracks in the soft ashes showed very little indication of side-slip. Indeed, it seemed practically impossible to cause the machine to skid, and this amazing performance, which effectively warmed up the engine, reassured us as to the stability of the vehicle as compared with a sidecar outfit. No sidecar we have ridden could have performed such evolutions without either skidding abominably or lifting the sidecar and passenger clean over the machine.

SPECIFICATION OF MACHINE:

Vertical Two-stroke (Rotary Valve) Water-cooled Engine, 76·2 × 63·5 mm., Three Speeds, Shaft Drive.

Triangular Frame with Nut and Bolt Fixings.

Bell Crank Coil Springing Fore and Aft.

Detachable and Interchangeable Disc Wheels.

Owing to the castor wheel steering, a reverse gear would be a dangerous inclusion, and our departure from the works further demonstrated the fact that a reverse is not really necessary. The machine can be pushed back a yard or two with ease, and it can be turned in such narrow compass that manœuvring out of difficult corners is as easy as with a motor cycle, while the direction of travel can be reversed on the narrowest of country lanes.

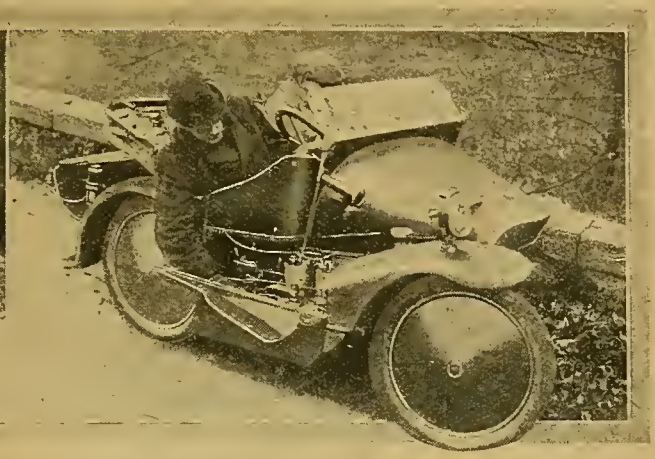
Protection from the Weather.

From Bradford we made our way over the moors to Ilkley *viâ* Baildon village, this mountainous route including one or two climbs as stiff as anything encountered in the ordinary course of touring. The climb through Baildon village was taken on middle gear till the final corner was reached, when it became necessary to drop into bottom.

A miserable drizzle had set in, and, halting by the old stocks, we decided to erect the hood. For the remainder of the day we left the hood up, travelling in the greatest comfort, in spite of sleet and atrocious roads. The glass screen of the sociable is about eight inches wider than that of a well-known make of light car, so that both driver and passenger are afforded excellent protection. A foot adjusted ventilator is provided for admitting warm air into the body from the radiator, while a handy little tray for gloves, pipe, matches, etc., is fitted in the dash. Nothing more snug, even in bad weather, could be desired.

Between Baildon and Ilkley we stopped and reversed our direction several times for the benefit of the photographer, and here we were able to appreciate the great convenience of the seat-starter. From the driver's seat one has complete control of practically everything—the petrol can be turned on, the carburetter flooded, plugs or the contact breaker examined, and finally the engine started by a pull at the handle, so that it is unnecessary to dismount for anything short of tyre troubles.

(1) Detachable and interchangeable wheels are provided. The self-operating jack shown is a useful accessory.



(2) Showing the accessibility of the power unit. Minor adjustments may readily be made from the driver's seat.

Doctors particularly will appreciate the unique advantages of this machine over the light car, its small points of convenience being specially attractive for all-weather stopping and starting work.

A Freak Gradient.

Baildon Dell is a really severe gradient, and, descending the hill, we found the brakes individually sufficient to skid either rear wheel. When applied together a very abrupt stop could be made, though both brakes were progressive and sweet in action.

Reversing our direction at the foot of the hill we essayed the climb, and on its low gear of 12 to 1 the machine proved irresistible. It could be driven at "tick over" speed on the steepest portions of the gradient, bounding forward at the least touch of the accelerator, and it was evident that the machine would climb practically anything where wheel grip was possible.

From Ilkley we made our way up the valley of the Wharfe to the picturesque village of Burnsall, Mr. Scott retaining possession of the wheel in order to demonstrate his machine to the best advantage. Snow, slush, and ice were encountered on the tortuous and hilly road, the conditions generally being against favourable demonstration. On this run our average speed worked out at 23 m.p.h., and we would put the maximum level road speed of the vehicle at 40-43 m.p.h., though both Mr. Scott and Mr. H. O. Wood claim to have attained over 50 m.p.h.

The Weight Question.

As regards road speed, it must be borne in mind that the weight of this experimental vehicle is very much higher than necessity demands, being exactly 7 cwt. This is partly owing to the fact that, aluminium being unobtainable, sheet steel is used throughout the body, while at no point has any effort been made to reduce weight, an extra load being desirable for test purposes.

In comparing the road performance of the vehicle with a sidecar outfit of 5½ cwt., we must therefore imagine the sidecar outfit to be similarly loaded, *i.e.*, carrying a load of four male passengers. Very few sidecar outfits would be capable of putting up an equal show with this load aboard, and in his final model Mr. Scott confidently expects to reduce the weight of the vehicle by at least 2 cwt.

The great weight of the machine was indicated by the falling off of speed on gradients. On the level it is as fast as a good sidecar outfit, but the latter would beat it on hills.

A Night Ride and Tyre Troubles.

After dinner at Burnsall a return was made through sleet, mud, and fog, and every degree of road and atmospheric unpleasantness, the hot air ventilator, the windscreen, and the hood being much appreciated. Such a journey by motor cycle would have been distinctly unpleasant, but the "home comforts" of the little sociable took no account of road and weather.

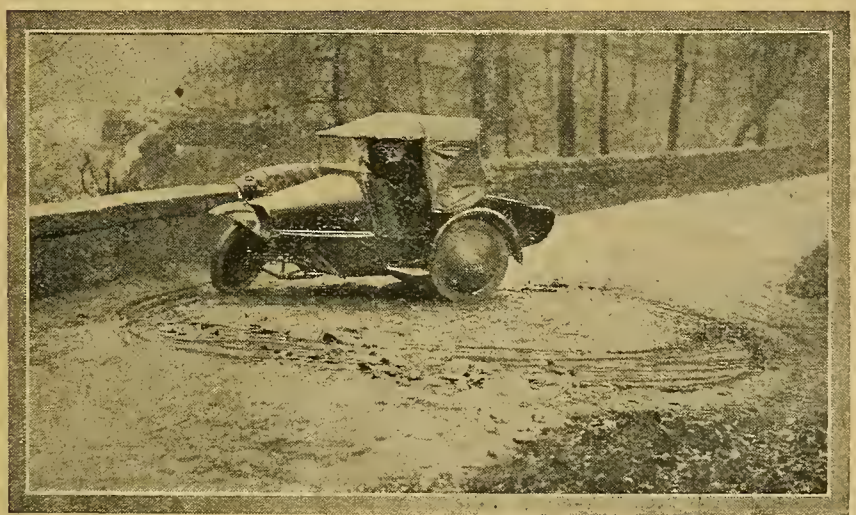
At Shipley the sidecar tyre burst with a loud report. A friendly policeman gave us the benefit of his flash lamp, and fitting the spare wheel was a matter of a few minutes only.

The machine was put away for the night in an unheated motor house, frost not being feared, as the aluminium water jackets were sufficiently elastic to allow for expansion. Petrol consumption for the day worked out at just under 50 m.p.g., which was agreeably surprising, considering road conditions and the weight carried.

The following morning we ourselves took control of the wheel, and from the outset found driving extremely easy. Being accustomed to car control, the right foot clutch and left foot accelerator at first required thought, but gear changing was so easy that a few minutes sufficed, and soon we were handling the machine over greasy setts in the Bradford traffic.

Efficient Springing.

The machine was first tried with passenger aboard, then solus. We had already formed an opinion as to the efficiency of the springing, and now that



NO NEED FOR A REVERSE.

The "handiness" of the Scott Sociable was exemplified on a comparatively narrow road, a complete circular turn being made without the least sign of wheel lift. Note angle of front wheel.

Road Test of a Scott Sociable.—

we came to sample the very worst productions in the way of West Riding pot-holes this opinion was amply confirmed.

The springing system really leaves nothing to be desired. It is far and away ahead of anything we have sampled in the way of sidecar or light car springing, which is a bold statement. Over a road of ordinary war-time pot-holes one can bowl ahead at full speed without the least discomfort. The body merely rises and falls with a steady swinging motion, there being no "dead stop" and sudden jar on encountering a bump of unusual severity.

Driven solus, the reaction of the springs was certainly more rapid than with passenger aboard, but we found that the sidecar wheel still showed not the slightest tendency to lift. Taken generally, Mr. Scott's system of bell crank springing, with coil springs which can be replaced in a few seconds in case of breakage, would appear to be a solution to the springing difficulty in connection with light vehicles.

Minor Points.

One or two minor points we would like to mention in connection with this test. In reply to a correspondent, we would say that the machine showed not the least difficulty in mounting from the camber of the road under the most trying conditions.

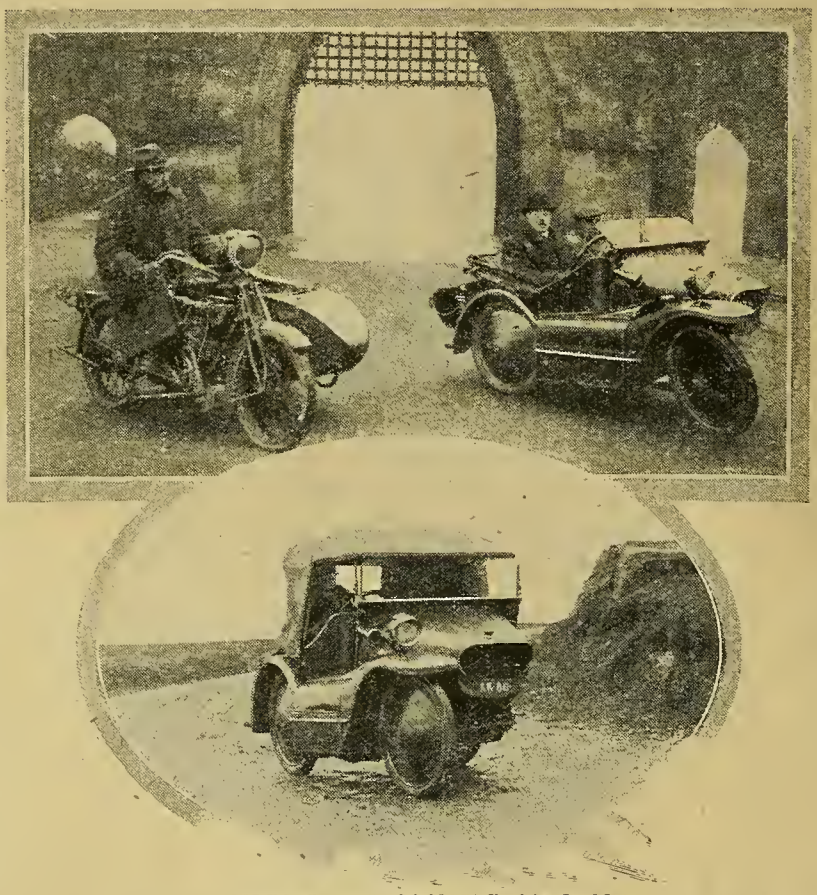
Roller bearings being used throughout, the engine can be run on an absolute minimum of lubrication. We noticed particularly that no smell of oil or hot engine is detectable, even when climbing long hills on bottom gear.

The steering is quick and effective, but on the crown of the road a distinct pull is felt towards the low side. This pull is particularly noticeable when descending gradients with the throttle closed, the idle engine then having a braking effect on the driving wheel, which tends to slew the machine to the right. Again, if the foot brake (sidecar wheel) be suddenly applied at speed, a strong pull to the left is felt, and it takes some little time to become used to the effect the brakes have upon the steering, which at first is somewhat tiring. One soon learns to use the brakes to the best advantage, however, and this is the only point which, during our test over the Yorkshire hills, appeared to us likely to present difficulty to the beginner.

The Power Plant.

The engine is a fine example of skilful and ingenious designing, which any practical rider would take a pleasure in maintaining, but though it is admirable as an engineering production, we are inclined to think that the man with no mechanical knowledge might fail to appreciate its merits. Half the secret in maintaining the tune of a twin-cylinder two-stroke lies in equal compression, without which the power falls off in a most astounding manner. Keeping an engine of this sort in concert tune is a matter of hairbreadths and mechanical judgment, but, since there is an ample reserve of power, the unmechanical rider would probably be quite content with mediocre tune. So far as our experiences go the engine is quite reliable.

The only other point we would criticise is the transmission, which, though remarkably sweet as regards the propulsion of the machine, is distinctly on the noisy side. Whether this noise is caused by imperfect gearing, or is simply owing to verberation on the steel body, which comes directly in contact with the gear box and the bevel casing, it was difficult to decide, but there was no doubt that the steel body had the effect of exaggerating the noises, which were most noticeable when the hood was erected.



SIDECAR AND SOCIABLE COMPARED.

(Top) A Matchless sidecar photographed beside a Scott Sociable. It will be noted that the riding position of the sociable is much lower than in the sidecar, and that its size is less than one might suppose.

(Bottom) This view emphasises the unconventional design of the Scott, as it was taken from a low viewpoint.

The New Model.

The lines of the new model are already decided upon, and Mr. Scott is confident that his alterations will remove the noise nuisance. In the first place, the engine is to be brought clean outside the body-work, while the cylinders are to be inclined outwards, thus providing still greater accessibility, and giving more room for the driver. The body is to be an independent and complete unit, constructed of three-ply wood—an air-tight structure, which is simply dropped into the frame, and can be removed in a few minutes.

A spiral bevel is to be used in place of the ordinary mitre bevel for the final drive, this being a compromise between the silence of the worm drive and the efficiency of the bevel drive.

For the interest of designers we would state that the wide field covered by Mr. Scott's invention is indicated by the official acceptance of the following claims:

(1.) Triangulated chassis and the more approved forms thereof, as applied *(a)* to *any* vehicle, and *(b)* to the three-wheeled type.

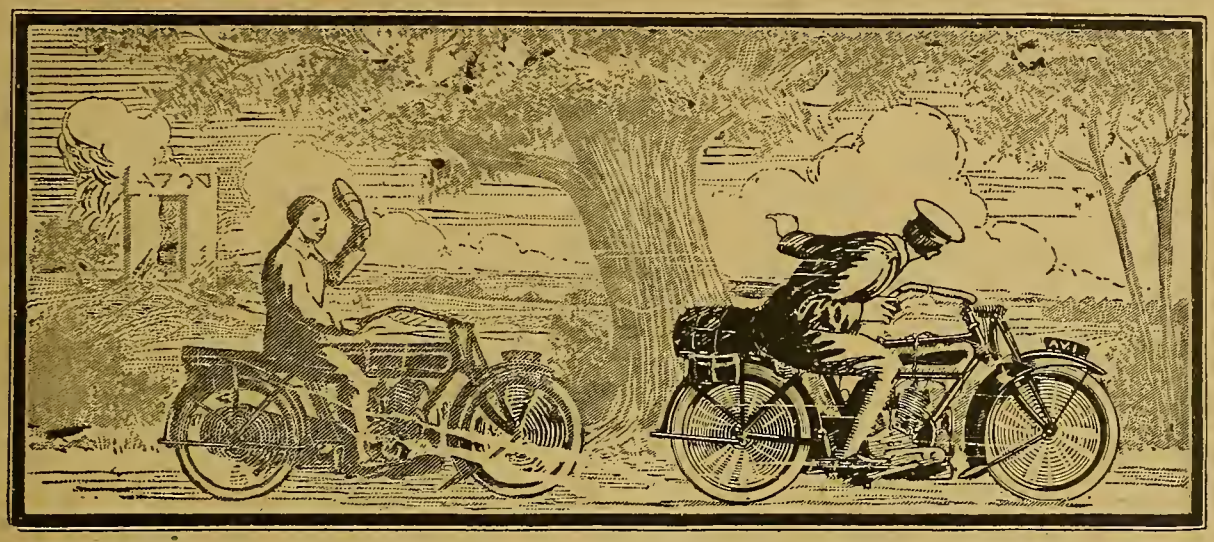
(2.) Various described alternative forms of chassis covering practically every type—as applied to a three-wheeled vehicle of the motor bicycle and sidecar type, in which all the wheels are offset, with front and back wheels approximately in alignment, and the engine located between these two wheels.

(3.) Front wheel bracket suspension, and alternative forms of rear wheel springing and control, as applied to three-wheeled vehicles.

These claims, it will be observed, deal more particularly with the frame design of the machine, and it will be recalled that the frame is built up from a number of eye-headed tube lengths, nut and bolt fixings being employed in place of brazed junction lugs. In case of accident a damaged tube can be removed and a spare telescopic tube put in its place.

This system of frame construction very much reduces production costs, while it eliminates the likelihood of frame breakage, such breakages generally being due to a tube having become burnt during the brazing process.

H.M.B



¶ The tourist or racer of yesterday is the despatch rider of to-day. He is naturally a connoisseur of the things that make motor cycling successful — and he welcomes such trusty equipment as Avon Tyres with lively recollection of "services rendered" in the good old days before the War. Sometimes he is good enough to write us — as, for example, the following from an A.S.C. driver at Zagazig, Egypt :—

¶ "Before proceeding to Ismailia I was stationed at Alexandria, and for two months I rode a 'Douglas' motor cycle fitted with Avon tyres. The roads were of the roughest — cobbles, sand, etc. — but, despite the hardest wear and tear, I experienced no trouble whatever with the tyres.

¶ "My work was delivering despatches, and the machine was very seldom at rest. No matter what part of Egypt I have been to, I have always found the greatest reliance is placed on Avon tyres."

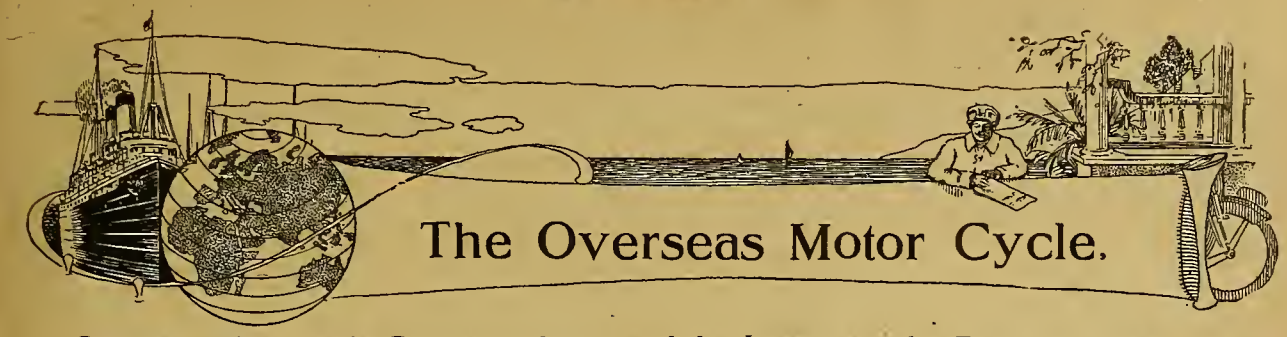
MOTOR BICYCLES
For Solo or Sidecar



The Overseas Motor Cycle.

Summary of a Year's Correspondence and the Lessons to be Derived Therefrom.

This article summarises the numerous lessons to be derived from a study of the expressed views of Overseas motor cyclists. Many British machines, though excellent at home, just fall short of Overseas requirements, and the suggestions and hints contained in a year's correspondence from practical riders should assist in the development of an ideal Overseas model or models.

"WHAT we need," writes an Australian reader, "is American standards of service in spares plus British standards in quality of goods."

When one comes to review a year's correspondence from Overseas readers this sentence strikes one as the keynote of at least ninety per cent. of the letters received, but the time being inappropriate, we do not intend in the following article to deal with the matter of sales and service. It is obvious that we shall have to be content with a very small share of Overseas trade unless, after the war, we can establish superior organisation for the benefit of the man who actually buys the machine: for while we may have the best motor cycle the world can produce, Overseas riders will content themselves with the second best if by so doing they are assured of superlative treatment and regular service of spares.

In the same pithy letter our correspondent adds:

> "What suits the Overseas rider will give perfect satisfaction at home, but what suits at home will very often prove quite unsuitable Overseas."

Nothing need be added to this concise summary of the general position of things from the point of view of the Overseas rider; he must have proper treatment and good service from the retail man; he must have a machine designed for really rough roads—strong, but not unnecessarily heavy.

Chain or Belt Drive for Universal Service?

Occasionally we receive letters stating that the chain-cum-belt drive leaves little to be desired, but the net total of the opinions received undoubtedly points to chain drive being in general favour for the universal Overseas model—the machine which is to give satisfaction in all countries and climates, and with sidecar or without.

The Overseas markets which present the brightest promise are, for the most part, tropical or semi-tropical, and the fact that belts are susceptible to climatic conditions very much limits their area of usefulness. In tropical lowlands it is found that rubber belts soon crack, owing to the temperature and dryness of the atmosphere, while leather belts are not entirely satisfactory as an alternative because of their grit-accumulating propensities, with resultant worn pulleys. In the hills the atmospheric conditions may be favourable, but here steep gradients, watersplashes, and rough roads demand a more positive form of drive. The total sum of opinions is, therefore, that the all-chain drive would give the most general satisfaction, and the question of open or enclosed chains now arises.

On the face of things, the enclosed chain drive would appear the more suitable and up-to-date, but there are several intermediate points to consider. Chain cases must be exceedingly well made and well designed if they are to warrant the extra weight and complication. If spring frames are to fulfil expectations by becoming the general order, then the difficulties of perfecting the rear chain case are much enhanced, and unsprung weight is increased. It would indeed require a well-made and well-anchored chain case to stand the racket of being attached to a wheel which followed every indentation of, say, a Rocky Mountains mining camp trail—and even with rigid-framed machines we have known so many Colonial riders who have disfigured their mounts from the outset by removing the back chain case, that we doubt whether this refinement would be generally appreciated.

The general opinion seems to be that the rear chain is as well left open (though adequately shielded) till more advanced designs have been made and tested at home. Open chains should be kept free of oil, stiff graphite being the only lubricant used. An oily chain readily accumulates grit, which forms into an ideal grinding mixture, soon wearing not only the chain but also the sprockets.

The front chain and clutch must, of course, be enclosed, and it is particularly desirable that ample ground clearance be given the front chain case. On one or two British machines, which are popular Overseas, the bottom of the front chain case is almost the lowest point, with the result that it soon becomes battered and a bad fit, probably touching the chains. The front case should be an aluminium casting, with good, wide, oiltight joints. If the frame were so designed that the engine-shaft, countershaft, and rear wheel spindle were all on the same line, better chain case clearance would be obtained, but in all present designs the countershaft lies below a line drawn from the engine-shaft to the centre of the rear wheel.

A dry plate countershaft clutch of ample diameter is probably the most suitable type, chiefly because it is not so susceptible to the ill effects of grit as the metal-to-metal type. The insets should be so arranged that they can easily be renewed when worn shallow, and every allowance should be made for full wear.

As regards clutch control, the following letter from Mr. H. C. Mansfield, Goulburn, N.S.W., is typical of many:

> "An h.b. clutch is a general advantage, as often we have to negotiate steep banks and stretches of sand, where it is impossible to ride; but with an h.b.c. clutch one can walk alongside, the clutch just sufficiently engaged to pull the machine."

There is no doubt that the h.b. clutch control offers enormous advantages, and with a duplicate foot control it would entirely fill the bill.

Engine Capacity an Open Question.

The question of engine capacity does not enter into this summary. The baby two-stroke, the small flat twin, and the 1,000 c.c. each has its place Overseas, and there is no doubt that Britain will establish an enormous market for her lighter types of solo mounts. In this line the British manufactures enjoy pre-eminence, and we shall undoubtedly see the light British colonial models holding their own against foreigners of double the power—and weight. Slightly better provision for cooling should, perhaps, be made than is necessary in England, but this matter rests as much with the producers of fuels and carburetters as it does with the manufacturers of cylinders.

Most British machines are at a great disadvantage Overseas on account of their shallow engine clearance, though this point has been rammed home so

The Overseas Motor Cycle.—

often that we need only attempt to emphasise its importance. Shallow ground clearance is the *bête noire* of the British sidecar machine abroad, and the number of letters we have received telling of damaged crank cases is surprising.

> Mr. F. Goodwill, Bangalore, writes that his 6 h.p. outfit "spoilt trade to the tune of £15 to £20 owing to its low clearance"; and
>
> "J.G.," Dolls Point, N.S.W., among numerous others, votes for a clearance of 7in., not only for the crank case, but for everything!

There is no doubt that this point alone will influence the decisions of hundreds of Overseas purchasers for just so long as British manufacturers refuse to consider their demands.

At all events the crank case should be protected by a bar of soft iron which can easily be renewed, and which is placed so that it intercepts any obstacle which would otherwise strike the crank case. This bar could conveniently carry the front footrests.

Mudguarding.

That mudguards designed on pedal cycle lines are hopelessly inadequate, we need hardly state, and wide, almost flat guards are obviously necessary. Great clearance is not necessary so long as the guards are wide and flat enough, so that mud cannot clog inside them. What the Overseas rider wants is wheel guards he can see inside and pass his hand round, and he also wants these guards to be attached to the frame in such a way that they almost form part of it. There must be no narrow lugs, filed thin at the edges, and no inaccessible nuts and screws, which jolt loose and are difficult to tighten. These wide, domed guards need to be made of very stiff metal, and arranged in such a way that, while not causing inaccessibility, they remain intact from the day the machine leaves the works till the end of its history. An annual coat of paint on the interior of the guard—the first coat being administered on the top of the works enamelling when the machine is new—will preserve the guards indefinitely.

Carburetters.

All carburetters should be fitted with an auxiliary air supply, giving a very wide range of adjustment to allow for the great differences in temperature and altitude.

> "T.C.H.," Nilgiris, India, emphasises this point, while most British Overseas possessions, which promise to become so important a market in the future, are subject to greater extremes than the British Isles.

The air intake should be of sufficient circumference to permit the use of an extremely fine filtering gauze, otherwise excessive engine wear may be caused by grit working into the cylinder and crank case *viâ* the carburetters.

> *Apropos* this Pte. A. Denby, Nowshera, India, writes that on one occasion he found the oil in his engine like gum, and thick with dust, while a gritty coating covered the flywheels and interior of the crank case.

Larger Petrol Capacity Needed.

A petrol capacity of at least sufficient for 180 miles is desirable, and the tanks of heavy machines should carry at least two and a quarter gallons. In some districts only four-gallon tins can be purchased, and one can imagine the inconvenience that would result from the possession of a tank holding less than half that quantity.

Mr. C. Vertue, Young, N.S.W., prefers ordinary turn-cock valves to screw-down needles, and our opinion entirely coincides with his. In hot weather, on steep gradients, or over rough roads, petrol is constantly oozing out at the point at which the needle passes through the tank, and much fuel can be lost in this way. To realise the extent of the loss one should fill one's tank with a heavy fuel, which does not vaporise on contact with the open air. In a few minutes one's knee-grips are saturated, and the fuel is dripping freely from the edges of the tank.

For Overseas use semi-T.T. bars might be fitted as standard, the touring handlebar being treated as the exception.

Sidecar Attachment and Design.

Sidecar breakages appear to be common, and we are as yet undecided whether the flexible type of sidecar chassis or the rigid type is the stronger. Four points of attachment are the minimum for any class of outfit in any land. Underslung chassis certainly do not appear to be popular Overseas. The sidecar mudguard needs to be specially well secured; if it were attached to the sidecar body instead of to flimsy and ague-smitten supports its chances of a long life would be very much increased.

In the Tropics coachbuilt sidecars do not appear to last, and the basket body is at present the only solution. The aluminium body may, in due course, solve the problem of looks *versus* usefulness.

Details.

Many detail improvements are necessary. Numerous correspondents write for larger tool-bags and better provision for carrying spares, etc. We in England feel the same pinch, and there is really no reason why so little room should be provided. A large flat tool-bag on the top bar of the machine, in addition to those carried aft, would be extremely handy, and the spare tube case might be sprung with the saddle.

The observation that all nuts should be secured, either with split pins or spring washer, is general, and it is interesting to note that every nut on the Clyno War Office machines is castellated and split-pinned. Something of this sort should certainly be done on Overseas models.

The Care of Bowden Wires.

Occasional correspondents complain of broken Bowden wires, but we would suggest that such breakages lie at the door of the owner rather than being due to any inefficiency in that much perfected production—the modern Bowden. Particular care should be taken that the wires cannot be pinched or called upon to operate through right-angle bends. If the controls work easily, and are provided with the necessary lubrication (preferably vaseline), they should last indefinitely.

> "J.L.W.," Sec.-Lt. 2nd A.D.B.D., B.E.F., writes: "I cannot understand why some well-known British machines still have the magnetos so close to the ground in front of the engine when there is plenty of room *behind* the engine."

There is food for thought in this reminder!

The Most Serviceable Colour.

As regards colour, E. Clarke, Churchtown, N.Z., prefers khaki, but we share the opinion of numerous other Overseas riders that black is the most useful "colour." It can be touched up from any tin of stove black or enamel without any difficulty in matching the shade, and ordinary stove black, thinned down with petrol, makes an exceedingly useful wet-weather waterproofing for plated parts. We do not entirely condemn a few plated parts on Overseas machines, as many riders (especially native gentry) like them, and those who do not like them can easily enamel them over. Correspondence from India emphasises the point that machines for that country should be of non-rustable finish, as during the monsoon one's mount is never dry for weeks.

Buckled Rims and Broken Spokes.

Buckled rims and broken spokes are almost a daily complaint, and one correspondent points out that footrests sprung with the saddle, Bat or Edmund spring frame fashion, would be a blessing. We would point out, however, that this system, though excellent at home, brings the footrests perilously near the ground with each downward motion of the rider—very much more so than an ordinary spring frame.

The position of the silencer needs to be chosen so that it does not lessen ground clearance, and the silencing should be reasonably effective, as much delay and bad feeling may be caused by an exhaust which frightens uninitiated cattle, etc., into a blind panic. An exhaust operated siren should be included, the handle-bars being kept as clear of fittings as possible. The front fork springs should be enclosed, as on the P. and M., and the rear wheel brake should be sufficiently adjustable to take up wear in the block—the simplest form of brake being the most popular.

PROHIBITION IN INDIA.

THE Indian Government is issuing a notification prohibiting the import of motor cars and motor cycles, with the object of checking the consumption of petrol and conserving the supplies for military purposes, and of liberating tonnage for more necessary commodities. Some indication of the volume of business done is shown in the import figures. During the period April, 1915, to April, 1916, Great Britain supplied motor vehicles to the value of £217,000, while imports from the United States were valued at £347,000.

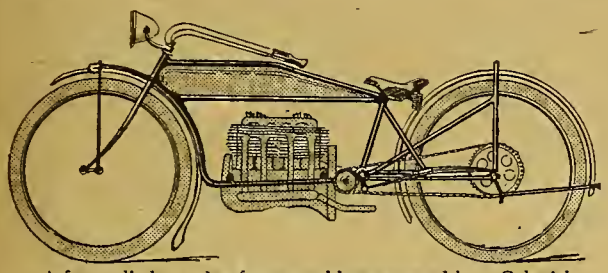
OVERSEAS OPINIONS.

A Further Selection of Letters from Readers scattered all over the World.

Spring Frame Design.

MR. E. PICARD, Hunter's Hill, Australia: "Having been a reader of your valuable paper for some years, I have followed with interest the articles on spring frame design.

"Out here in Australia spring frames are commanding great attention, and, if English manufacturers wish to do any business in the future, they must devote more attention to this problem. Another point they want to study in Colonial models is power. Why they cling to their puffing 3½ h.p. 'buses I cannot understand; 28in. wheels are an important addition also.



A four-cylinder spring frame machine suggested by a Colonial reader. (See E. Picard's letter.)

"I am enclosing a rough design of what I consider an ideal Colonial model, having a four-cylinder engine of about 8-10 h.p., a long wheelbase, laminated springs, fore and aft, of such strength that, when the rider's weight is taken, the springs sink to the same extent—not the front springs stronger, as I have seen on a certain well-known American machine.

"You will see that I have incorporated full cantilever rear springing, this giving a more supple motion than the quarter elliptic. At the centre of the spring anchorage would be a rocking shackle, also a link at the frame end beneath the seat-pillar. Twist wrist control is ideal, not being so tiresome as the lever method.

"With such fitments as mechanical lubrication, mechanically operated inlet valves, a tank of ample capacity, chain drive, and a two-speed gear, this should prove a machine well sought after by Colonials who have had to put up with stiff under-powered machines—probably suitable for smooth English road conditions only."

Carbon Deposit.

"W.G.Q." Punjab, India: "Two years ago I took up motor cycling in earnest, as an aid to my inspection of work over large areas in the Punjab. I purchased a 2¾ h.p. A.J.S., and though I am an engineer, sad to say, owing to lack of practical experience in driving, I underoiled, and I had no carbonisation troubles. In 6,000 miles I took the engine down twice, and found very little deposit. My only trouble after the above mileage was a loose small end. As my 2¾ h.p. did me so well last year, I bought a 1915 6 h.p. model with sidecar. In 3,900 miles I gave a pumpful of Mobiloil 'B' every two and a half miles and every one and a half miles in the first 100 miles. (Owing to climate more oil is required in India.) At the end of 3,900 miles I took the cylinders down as the compression was poor, though I had plenty of power. I was at once convinced of the truth of the adage about leaving well alone. The rings were highly polished all round, the gudgeon pin was almost a driving fit, there was no play anywhere, the rings were quite free, and the carbon deposit was negligible. My only trouble was pitted valves. The time taken in dismantling and reassembling was practically wasted. I ground in the valves, and compression at once returned.

"The A.J.S. 1915 engine is, of course, a very fine engine, and it may be exceptionally so, but there must be many other well-known engines which give similar results. Two-strokes may require decarbonisation after every 1,000 miles. Many owners, I believe, find 600 miles the limit, but the four-stroke engine as used on cars and motor cycles for years is streets ahead of any two-stroke ever invented as regards carbonisation troubles.

"Finally, it may interest readers to know that my A.J.S. engine after 3,900 miles had more carbon on the front cylinder and piston than on the back one. The deposit was very little; but still, those who suffer from dryness in the front cylinder might make a pilgrimage to Wolverhampton and buy a bicycle which has an engine made by Messrs. Stevens. Usual disclaimer."

Cleanable Sparking Plugs.

MR. J. M. SMITH, Bloemfontein, South Africa: "One of the most satisfactory sparking plugs I ever owned was a Peto and Radford. It had a disc on a stem for the electrode. It was easily taken to pieces to clean, and was a very fine plug, so much so that I have often wondered why that system of construction was abandoned.

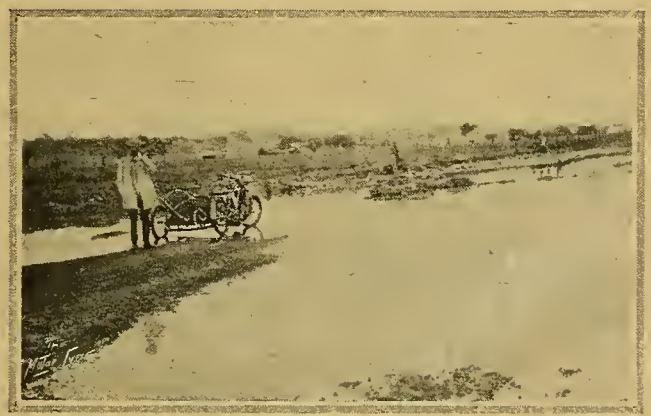
"Some time ago my machine (1913 P. and M.) would not start, in spite of many attempts. At last I borrowed a plug (I had tried two or three before that), and it went off all right, so it was the plug at fault. I washed or soaked the plugs in petrol for five hours, and cleaned them thoroughly, but with no result. I then got desperate, and, after thinking for a while, took out the central wire (Bosch plugs), lit the Primus stove, and heated the body of the plug (porcelain), etc., red hot. When they cooled I put them in, and the engine started first kick. I do not say this will do for all plugs, but I reckon it will do for most, and, anyway, it is worth trying. If it does no good it will do no harm.

"I may say I date back to the days of the good old ordinary bicycles. My first mount was an Ariel—the one with the levers and screws inside the wheels to tighten up the spokes."

A Wet Main Street.

MRS. T. E. CUNNINGHAM, Sydney, N.S.W.: "I am sending you a photograph of a Scott, taken while travelling under difficulties in an 'out back' part of New South Wales. This is a main street of a country town under water during wet weather. During this trip nothing was kept dry except one pair of pants, which, when they arrived at a town with an hotel in it, the two men had to borrow and lend, one going out for a shave while the other stayed in bed. It put me in mind of the time when one of them came rushing down the side of a mountain and ran straight into a river—motor cycle, clothes, and everything—and, after getting the machine going again, had to travel twenty miles before coming to any habitation at all.

"Mr. Cunningham is a very enthusiastic rider, and has been for a number of years, and has ridden a large variety of solo machines. But since purchasing combinations I think I have owned and ridden in as many different makes of sidecars as any lady in Australia. Most of our friends keep their machines from year to year, but it is characteristic of Mr. Cunningham to change about. The A.J.S. is no longer with us, our latest being an 8 h.p. water-cooled Williamson. But I will never forget the A.J.S.: it was splendid."



A Scott sidecar encounters floods in a "main street" of a country town "out back" in N.S.W. (See Mrs. T. E. Cunningham's letter.)

TIMES TO LIGHT LAMPS.

GREENWICH TIME.

Jan.	4	... ...	4.32 p.m.
,,	6	... ...	4.35 ,,
,,	8	... ...	4.38 ,,
,,	10	... ...	4.41 ,,

Daylight Saving Again.

April 1st is suggested as the date for Daylight Saving to commence this year—much earlier than last year.

War Models.

Several manufacturers are expecting to share in a large order for powerful motor cycles, with and without sidecar attachments, required for the Russian Government.

Another Stolen Motor Cycle.

£10 reward is offered by Sec.-Lt. Cecil C. Clark, R.F.A. and R.F.C., for the recovery of his 1915 3½ h.p. all-black T.T. Sunbeam fitted with a B.S.A. carburetter, Bosch magneto, and Lucas lamps, which was stolen from an aerodrome in Yorkshire.

American Impressions of the Scott Sociable.

America appears to have been favourably impressed by the Scott Sociable. The coloured cover picture of a recent issue of the *Scientific American* shows two Scott Sociables amidst artistic rural surroundings. The picture is headed "A Motor Car for the Multitude—A Recent Development of the Motor Cycle."

Motor Cycle Police in Australia.

Motor cycles are now being adopted by the Traffic Police Department of Australia. The mounted constables wear a uniform of neat-fitting khaki with tan leggings and boots (says *The Motor in Australia*), and the new units are distributed about the various suburbs, including Randwick, Kogarab, and Chatswood.

Let us hope that the British police will follow the example of the more progressive Colonial.

Increased Railway Rates and the Motor Cycle.

Now that railway services are reduced and passenger rates increased to 1½d. a mile, there should be no doubt, even in the minds of the most sceptical, that the motor cycle offers not only the most convenient, but also the cheapest, mode of travel. These new conditions should have a distinctly enlivening effect upon the second-hand market, and, new machines being unobtainable, owners with good second-hand mounts for sale will find an excellent market this spring.

Excessive Zeal at Stratford Court.

Recently a photographer of our staff was convicted at the Stratford Court House in London for exceeding the speed limit with a motor cycle and sidecar, the Bench imposing a fine of £5. The defendant asked whether he might go to his home and procure the balance, but apparently the magistrate made no reply, and the police in court promptly put the unfortunate motor cyclist into a cell, where he was kept for an hour and five minutes. During that time the police telephoned to our Tudor Street offices, and a member of the staff at once went to Stratford Court with the money.

In view of the fact that the original summons had been served on the defendant at his home address, which was, therefore, verified by the police, and further that he offered to leave either his motor cycle and sidecar (which stood outside the court) or his gold watch in charge of the police till he obtained the money, we need hardly ask whether, in the opinion of our readers, the steps taken were rather too drastic.

An Expression of Regret.

We are informed by the Commissioner of Police that, as the magistrate did not allow the defendant time to pay the fine, the police action in the matter was quite in order, as the gaoler was acting not as a police officer, but as a servant of the court under the magistrate's directions. An expression of regret for the inconvenience and delay caused is subsequently included in the Commissioner's letter.

SPECIAL FEATURES:

VOLUNTEER MOTOR CYCLISTS' SPEED TRIAL.

OVERSEAS NEWS AND VIEWS.

ROAD TEST OF A SCOTT SOCIABLE.

New American Sidecar Record.

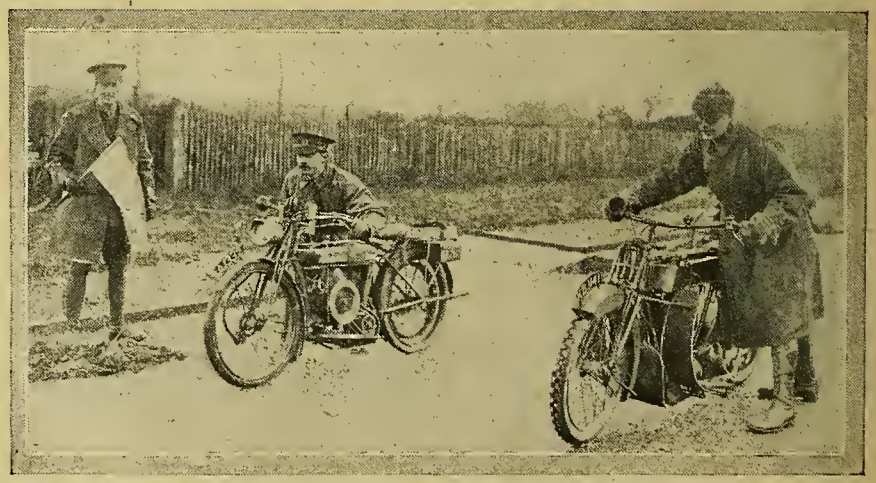
A new twenty-four hours sidecar record has been established in the United States. Two Indian riders covered the 584 miles between Springfield and Montreal, which necessitates crossing the Adirondacks, in 19h. 27m.

A Prospering New South Wales Club.

The Lithgow Motor Cycle Club appears to be making rapid headway, and many new makes of machines have recently made their *début*. Mr. "Bob" McGarry appears to be a very active member, and it is quite refreshing to read about the fine weather, hill-climbs, and reliability trials which the energetic members of this club are organising.

Home Devised Lighting Set.

One of our readers has fitted up an old low-tension magneto, originally belonging to a F.I.A.T. car, as a lighting set for his sidecar outfit. The arrangement has worked excellently for some months, and though the lights flutter a good deal no lamp troubles have been experienced. The lamps are connected direct to the magneto, no batteries being used.



NORTH-WESTERN VOLUNTEER MOTOR CYCLISTS' SPEED TEST (see page 15).
F. Thackery starting F. A. P. Zacharius (7 h.p. Sunbeam) and F. W. Mainey (2¾ h.p. Douglas). The former won, but owing to the state of the road could not "let out" his Sunbeam to its limit.

The National War Funds.

At the week-end the principal war funds stood as follow :

British Red Cross Fund	£5,755,692	0	0
Tobacco Fund	123,073	0	0

Curious Damage.

A reader in the R.F.C. sends us a photograph of his machine after trying conclusions at speed with a 45 h.p. car. The impact knocked the cylinder clean off the machine, leaving the cylinder base plate securely bolted to the crank case. The rider luckily escaped unhurt.

A Kindly Act.

On Saturday last Mrs. C. A. Vandervell entertained 400 wounded from the Roehampton Hospital in the canteen belonging to Messrs. C. A. Vandervell and Co. The men arrived at twelve o'clock, and after an excellent dinner they were entertained to a first-class concert.

Safety First.

The Commercial Motor Users' Association have made the following recommendations in view of the Safety First campaign. A driver intending to stop or slow down should hold up his right hand. Previous to turning to the right he should hold out the right hand horizontally. Previous to turning to the left he should hold the right hand up or extend the left arm in such a position that it can be seen. In crowded traffic vehicles should be kept under close control. In turning corners to the right a wide sweep should be taken. When turning to the left the driver should turn close to the kerb. A Safety First kinematograph film, prepared by the London General Omnibus Co., is being shown at each performance at the London Coliseum.

A Special Case for a Special Constable.

Verily the duties of a motor cyclist special constable are many and varied. A recent duty of W. H. Carson, the Excelsior manufacturer, who is a sergeant in the Coventry Special Constabulary, is, however, probably without parallel. Last week a telephone message was received at the police office that a man who had imbibed too freely was creating a disturbance. Mr. Carson at once transported a constable to the scene. The man proving unruly, he was put into the sidecar, and the fourteen stone constable sat on him, and thuswise the police station was reached in record time for such cases.

The German Petroi Haul (?) in Rumania.

Mr. Watson Rutherford, M.P., presiding one day last week at the annual meeting of the Rumanian Consolidated Oilfields, Ltd., said that he had just heard that the British Military Mission had carried out at the last moment everything possible to ensure the utter destruction of the company's wells. Everything had been rendered useless either to the enemy or anyone else. The petrol captured by the enemy was less in value than he would have been able to obtain by buying from Rumania during any corresponding three months since the war began. The German papers are furious at the efficient manner in which the oil wells in Rumania have been destroyed. An officer on the German General Staff says, "Whatever could be ruined has been ruined," and, needless to say, we are very glad to hear it.

Tendencies of Design in U.S.A.

An article in Wednesday's issue of *The Light Car* on light car design at the New York Show demonstrates the fact that, like American designs of motor cycle, the American light car is gradually assuming a European conformation, particularly with regard to outward appearance. Thus history repeats itself. The early American pedal cycles were a law unto themselves, but gradually and surely they embraced many British features, until to-day there is practically little difference between the two countries.

Unpleasantly Seasonable Roads.

The roads in many districts over the Christmas holidays, especially in the Midlands and North, were in an almost unrideable condition, owing to thick ice caused by the half-melted snow which had refrozen. While frozen hard this type of surface was bad enough, but when on Thursday it became covered with water it was practically an impossibility for a solo machine to stand up on it. Many motorists state that never before have they experienced such treacherous surfaces. One rider of over ten years' standing took three and a half hours to cover a distance of eight miles on a solo motor cycle. In this distance at least twenty spills resulted, and at the completion he was forced, for the first time in his motoring experience, to give up owing to road conditions and complete the journey by train.

A Budding Juvenile Designer.

Our illustration is abstracted from a Bristol newspaper. It formed an amusing result in a Christmas drawing competition for children. We do not wish to belittle the efforts of any youthful artist, but he has succeeded in portraying a D.R. mounted on the most astonishing type of Douglas machine we have ever seen. Douglas riders will

laugh at the many mechanical inaccuracies—a flywheel below the engine, a cased-up back cylinder, novel spring forks, an invisible drive, and a real study in frame design.

Nevertheless the attempt is not bad for, we presume, a lad of about 12 years, and we urge him to persevere in his artistic efforts.

An Unusual Trouble.

A reader relates an experience which has its moral. Whilst in Devon recently one of the cylinders of his machine blew in halves four fins from the bottom. The engine, it so happens, was not of British make, and on telephoning the agency our correspondent was informed that no front cylinders were in stock. The trouble was later diagnosed by the agent's expert as resulting from a tiny crack caused by a seizure. The owner is confident that no trouble of the kind occurred during his ownership of the machine, and the agency retorted that the seizure must have occurred during its road testing, and in any case that it might have been so slight that it could be taken for a misfire or a partial petrol stoppage.

Some Contents of this Issue.

We commence this new volume of *The Motor Cycle* with several exclusive features of general interest. Firstly, Overseas motor cyclists will find much to attract them. The Scott Sociable, which created such a furore at the time we described and illustrated it in these columns, has now been put through its paces in Yorkshire by a member of the staff, and his impressions are published, whilst two other exclusively illustrated features include an account of a Volunteers speed trial in the North-western district, and particulars of a new 4 h.p. twin Excelsior for one of the Allied Governments.

There are many other items of news in this comprehensive issue.

A Weird Experience.

Major T. W. Loughborough, the secretary of the Auto Cycle Union, while on duty with the Surrey Volunteers the other evening, was driving his 7 h.p. Matchless and sidecar at a very slow speed, when he gently bumped into a pillar-box at a point where three roads joined. He dismounted to examine one of the roads and see if it were the one he wanted to take, and then, as he thought, crossed over to where his machine was, only to find that he had lost it completely. After groping about for twenty minutes, he had to call in the aid of a passing cyclist before he was able to discover it. This is one of the weirdest fog experiences of which we have heard.

Bearing Pressures.

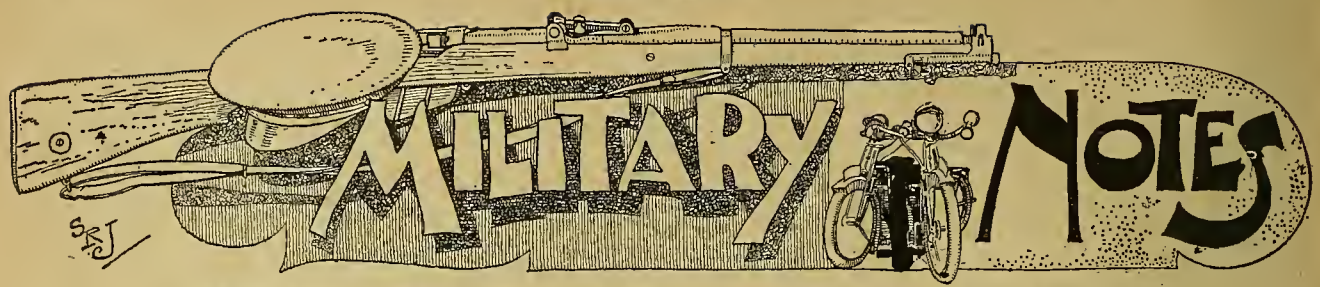
With reference to the article which appeared on the above subject in our issue of October 19th Mr. Norton sends us the following letter received from a German in an internment camp in the Isle of Man :

"May I be allowed to mention that the value of the 27 lb. given in the second formula is not quite correct, as it should be 30.261 lb.? Being a designer of high-speed petrol engines myself, and one who takes a special interest in the long-stroke type, I trust that you will pardon me for trying to uphold the name of your famous engine. Of course, there is no doubt that other people besides yourself have found the error out, but I simply took the matter up for the reason mentioned above. The formula given for the pressure or force required is $P = \frac{wv^2}{gr}$. The value of v^2 in the case of the 96 mm. stroke engine is equal to

$$\left(\frac{96 \times 3.14159 \times 1500}{60 \times 25.4 \times 12}\right)^2 = 611.93.$$

$$\text{Then } P = \frac{0.25 \times 611.93}{32.2 \times .157} = 30.261 \text{ lb.}$$

"If I had the necessary writing space at my disposal I would write something more on main and gudgeon pin bearing pressures.—PAUL A. HIPPERMANN."



A FEATURE COMMENCED IN "THE MOTOR CYCLE" OF MARCH 21st, 1910.

THANKS!

WE have to acknowledge, with many thanks, the receipt of a number of Christmas cards and New Year greetings from all over the world. Particularly gratifying to us is the selection of cards from readers in the Services; some of them were exceedingly well-timed (incidentally, a motor cyclist was always known for good timing!). A day or two before Christmas, cards arrived from Afghanistan, Macedonia, Egypt, Poona (India) (Sergt. A. J. Sproston, R.E., sends his best wishes to all the "boys" at home, adding a grateful thought for the fallen), whilst from Austria there was a card from Basil Vickers-Jones, who has been interned in Lower Austria since the commencement of the war. Vickers-Jones held an important position at the Bavarian works of the Premier Co. before war was declared, and was interned with other British residents. He wrote us six months ago asking for motor papers to interest the members of a motor class of British prisoners. We were only too happy to fall in with the suggestion; but, sad to relate, the parcel was refused, and the letter returned marked, "Interned in enemy country. Cannot be delivered."

It has pleased us very much to receive a number of cards from readers on the French front, some of them from men who were recruited by the Editor of *The Motor Cycle*. Among the men in the Services who send us greetings are such well-known names as Lt. T. E. B. Chalmers, A.S.C.; Lt. T. Woodman, R.F.C.; Cpl. W. Pratt, M.G.C., H.S.; Sgt. Cyril Williams, R.E.; Cpl. T. E. Greene, A.S.C.; — F. C. Dee, R.G.A.; Pte. J. F. Spencer, A.S.C.; Sgt. Howard R. Lane, A.S.C.; Flight-Sgt. J. G. Nixon, R.F.C.; Pte. Maurice Greenwood, A.S.C.; and the regimental card of despatch riders of the XIII. Corps, bearing the names of twenty-three motor cyclists with whom "*The Motor Cycle* is a great favourite, and there is always a big rush for each copy," to quote Cpl. J. B. Morris.

WITH THE M.M.G.S. IN INDIA

SERGT. A. FIELDER, M.M.G.S., India, sends the following greeting: "Just a card to wish you and the 'Blue 'Un' a prosperous New Year. I can assure you that *The Motor Cycle* is an old friend of the battery, as practically all of us were constant readers before the war." Sergt. Fielder will be remembered as an old New Hudson trials rider.

Sgt. A. Fielder.

PHOTOGRAPHS FROM NEAR AND FAR.

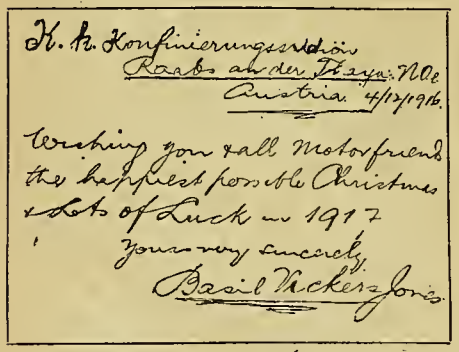
ONE of the most pleasing features in the publication of the many exclusive photographs from the war zones which are reproduced in *The Motor Cycle* is the recognition by relatives of their dear ones. A letter this week is from the wife of a despatch rider seen in one of our pictures who is now in Egypt, having been to Mesopotamia and India. The lady in question, in writing for a copy of the photograph, mentions that before parting she had strict instructions to send *The Motor Cycle* to her husband every week.

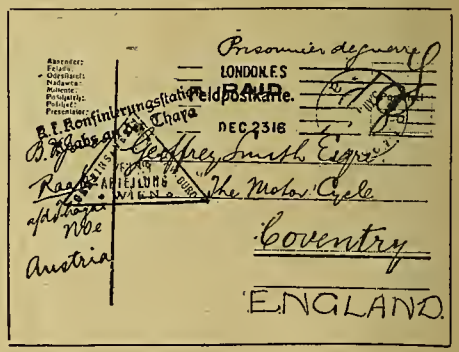
PRICES IN THE WAR ZONE.

THOSE motor cyclists who report paying sums up to 2s. for copies of *The Motor Cycle* in the different war zones may be interested to know that Cpl. P. L. Cearns, R.E., writing from France, says that *The Motor Cycle* is eagerly read by the motor cyclists of his section; none of whom has ever paid more than 3d. for a copy.

NEWS OF A PIONEER MOTOR CYCLIST.

WE recently received a letter from that old-time rider of a Vindec, Tom Woodman, who is now a Lieutenant and Officer in Charge Transport, Kite Balloon Co., R.F.C. He says, "No doubt you will be surprised to hear from me taking part in this very interesting man shoot. I am mixed up in the Air Service, and have plenty to do with all sorts of motor-propelled machines. At the moment I am in hospital with injury to the ribs, but hope to be out in the course of a day or two; inactivity is not my *forte*. We never thought twelve years or more since that motor engines would do what they are doing to-day. Anyhow, the mysteries keep unfolding themselves."





FROM AN OLD-TIME COMPETITION RIDER, NOW PRISONER OF WAR IN AUSTRIA.

From all parts of the globe we have received Christmas and New Year's greetings, not the least gratifying being a number from appreciative readers in the trenches. Among the most interesting is a greeting card from Basil Vickers-Jones, who is interned in Austria. He will be remembered as a competitor in T.T. races, his mount being a 90° twin Premier.

A SCOTTISH TRIALS RIDER.

MANY of our readers will recall A. U. Russel Downie, of Edinburgh, who figured frequently in northern competitions, including the Scottish Six Days Trials. His mount was usually an A.J.S. machine, upon which he set up several notable performances. Downie is now in the Royal Naval Air Service, which he joined at the beginning of 1916. His photograph accompanies this note.

A. U. Russel Downie, Royal Naval Air Service. He will be remembered as a prominent rider in Scottish Six Days Trials.

HIGH PRAISE FOR THE TANKS

MUCH has already been written regarding the utility of the "Tanks" for field use, but in the despatch reviewing the Battle of the Somme, General (now Field Marshal) Sir Douglas Haig says:

"The part played by the new armoured cars—known as 'Tanks'—in some of the later fights has been brought to notice by me already in my daily reports. These cars proved of great value on various occasions, and the personnel in charge of them performed many deeds of remarkable valour."

A MIDLAND OFFICER.

W. H. H. SHELDON, the Regal rider, of Birmingham, is now a second-lieutenant in the A.S.C., M.T. Previous to joining this section Lt. Sheldon served two years in the Royal Engineers as a despatch rider, and he was moved to write to us by the publication in the issue of December 14th of the photograph of Ernest Smith, a former partner of his, and the one and only Jack Woodhouse (now a Flight Commander), in the Regal business. Sheldon rode a Green machine in the last Junior T.T., and has also figured with success in a number of Midland motor cycle competitions.

MOTOR CYCLISTS' KEENNESS.

THE accompanying photograph is of a motor cyclist quartette attached to one of the Divisional Field Ambulances. The picture was kindly sent to us by E. G. Mackenzie, who writes as follows:

"Doubtless the picture will interest you. Obviously the machines are good old Triumphs, three being 1915's, and my own mount a 1916. Reading from left to right the riders are: G. Caley, D.C.M., Hopkins, Mackenzie, and Murphy, known as 'Spud.' I have been riding out here since September, 1914, and all my pals run me pretty close. All our machines have been over newly captured ground. We are all quite keen on our jobs, and would under no circumstances change with anyone out here."

A MIDLAND CLUB SECRETARY.

AMONG the Christmas greetings we received was one from Howard R. Lane, now a sergeant in the A.S.C., M.T., who for a considerable period was secretary of the Sutton Coldfield Automobile Club. Sgt. Lane is still in France, and is attached to an A.S.C., M.T., lorry park, where he has been for many months. He, like many other motor cyclists, is eagerly looking forward to the return of competition days.

Sgt. H. R. Lane.

PROMOTIONS.

IN last Monday's *Gazette* we noticed that Flight-Lt. L. P. Openshaw, R.N., has been made a Flight-Commander; also that Flight-Sub-Lt. W. G. McMinnies, R.N.A.S., has been promoted to the rank of Flight-Lieutenant. Temp.-Capt. S. W. Carty, A.S.C., and Lt. Leslie Gamage have been awarded the Military Cross.

Motor cyclists attached to the Divisional Field Ambulances astride Triumphs. Reading from the left the riders are: G. Caley, D.C.M., — Hopkins, E. G. Mackenzie, and — Murphy.

Racing at Gatooma, South Rhodesia.

British Motor Cycles occupy a Prominent Place in the Results.

A MOTOR cycle race meeting was held at Gatooma, S. Rhodesia, on the 12th November last, the races being run on the Gatooma-Golden Valley Mine Road, which provides a stretch of 11½ miles of fairly good going.

The first race to be run was the District Championship for all machines, and the following riders lined up: Reynolds (4¼ B.S.A.), Ross (4¼ B.S.A.), Dawson (6 Enfield), Reacord (5 Indian), Juul (5 Indian), and Lang (7-9 Powerplus Indian). Lang fell in cornering at speed, and the following results were obtained:

	Av. speed.
1. Dawson (6 Enfield) ...	48.5 m.p.h.
2. Reacord (5 Indian) ...	46.5 ,,
3. Ross (4¼ B.S.A.) ...	36.4 ,,

The second race was a One Mile Handicap on horse-power, and was run over a different section of the road, the following machines being entered: Reynolds (4¼ B.S.A.), Ross (4¼ B.S.A.), Dawson (7-9 Harley-Davidson), Juul (7-9 Powerplus Indian), Reacord (5 Indian), and Dawson (6 Enfield). Juul (7-9 Indian) came in first, while Reynolds (4¼ B.S.A.) obtained second place.

The 11.7 Mile Handicap (on h.p.) drew seven entries, but unfortunately Lang (7-9 Powerplus Indian), who was scratch, again came off at one of the corners and cut his arm badly. Winners:

1. Reacord (5 Indian) ... 12m. 50s.
2. Dawson (6 Enfield) ... 12m. 10s.

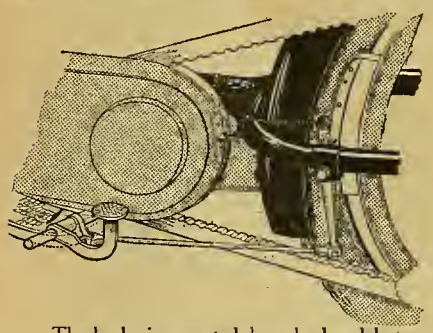
Dawson's speed averaged 57.6 m.p.h., which was a good performance, as the track was far from perfect.

In the afternoon a potato race, with ladies occupying the sidecars, and musical chairs, caused great amusement, and the meeting was voted a thorough success.

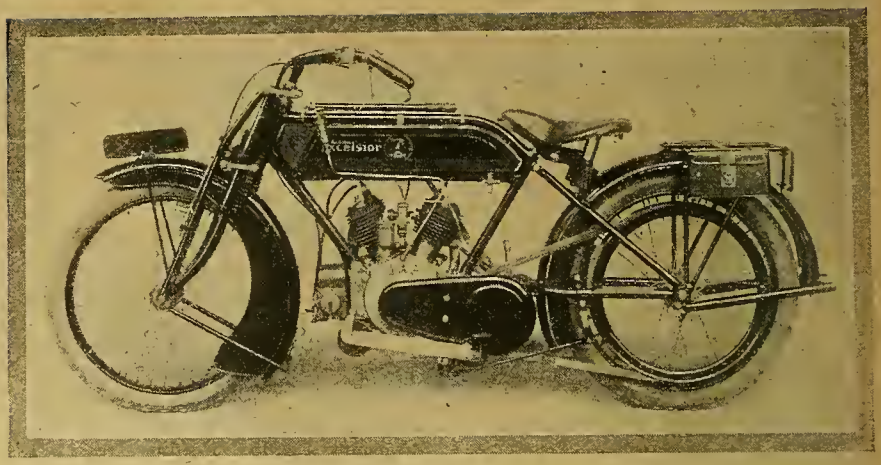
A NEW TWIN EXCELSIOR.

A Twin-cylinder Machine Designed for Overseas Purposes and Used by the Allied Armies.

MESSRS. BAYLISS, THOMAS, AND CO., manufacturers of British Excelsior motor cycles, have recently introduced a new twin-cylinder model, which will probably supplant the big single which has done duty under this old and respected name as a very taking double purpose mount. This new model is designed to meet military Overseas requirements, and possesses several excellent features, though in general design it follows standard practice. Very special attention has been paid to the mudguarding, and, the machine being built for use in a rough country, a ground clearance of 6in. is provided. The specification includes the well-tried Sturmey-Archer countershaft three-speed gear, adjustment for which is provided, 2⅜in. Dunlop tyres, B. and B. or Amac carburetter, and Druid new pattern forks. The wheelbase is 56in., and the height of the saddle 30in.



The brake is operated by a heel pedal at the rear of the left footboard.



The new 4 h.p. twin Excelsior, fitted with three-speed Sturmey-Archer countershaft gear, and chain-cum-belt transmission.

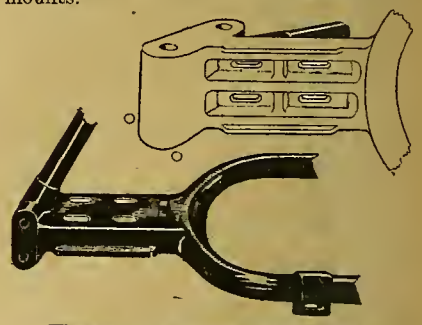
Chain-cum-belt Transmission.

The 4 h.p. J.A.P. engine, of a bore and stroke of 70 × 64.5 mm. (496 c.c.), has been selected. This engine is of the same dimensions as the 3½ h.p. model, but is provided with larger flywheels, which renders it better suited to sidecar use. Chain-cum-belt transmission is employed, the countershaft pulley being of sensible diameter, and the chain, of course,—enclosed. The rear wheel brake is a thoroughly well-designed mechanism, and possesses any amount of retarding effect. It is operated by a heel brake on the left footboard.

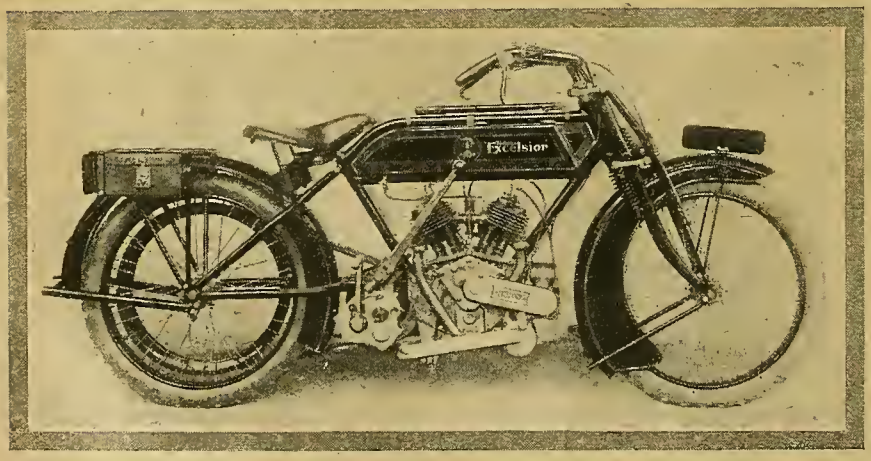
The machine generally conveys an impression of solidity. The clutch, it will be observed, is controlled from the handle-bars, and the change speed lever is well situated and of sensible size.

There seems to be some doubt as to the possibility of immediate delivery of this model for private use, but we understand that other Excelsior models on somewhat similar lines are at present under course of construction. The model illustrated is by this time in the hands of the French Government.

The adoption of a medium powered twin by the Excelsior firm is a sign of the times, as this company has hitherto paid special attention to single-cylinder mounts.



The gear box bracket, showing slots provided for adjustment.



The capacity of the engine is 496 c.c. (70 × 64½ mm.). Although the capacity of the engine is the same as the 3½ h.p. J.A.P., the flywheels and crank case are larger, a feature conducive to smoother running.

A DUTCH CLUB TRIAL.

WHILE we in England have now no thought of holding trials or races, our neutral friends the Dutch continue to hold competitions of various kinds. One of the latest was a reliability trial consisting of a run over the Dykes. The weather conditions were most unpropitious, and the roads were in an appalling condition, which probably accounted for the small number of starters, viz., fifteen. Starting and finishing at Amsterdam, the course measured forty-one and a quarter miles.

The idea of the run was for the competitors to adhere to schedule time, while the particularly tricky route had to be followed by means of special maps. All experienced great trouble in ploughing through the mud, and most had falls. The first to finish came in at 12 noon (the start was at 9.30 a.m.), but none succeeded in adhering to the schedule.

The winner of the highest award, viz., the gilded silver medal, was P. J. Kestuen, on a 7 h.p. Indian. Of the three British machines entered, the James two-stroke, ridden by W. H. Wellensech, was the only one to start, and obtained a silver medal.

The following also gained awards:

S. Birnbaum (American Excelsior), bronze medal.
M. C. v. d. Wal (American Excelsior), silver medal.
F. J. Visscher (7 Indian), silver medal.
C. F. G. Eijkelen (7 Harley-Davidson), bronze medal.

A Volunteers' Speed Trial.

R. B. Stevenson (3½ h.p. Rover sidecar) winning a heat at the meeting of National Motor Volunteers on the new road near Birkenhead.

MOTOR cyclists of Liverpool and district have long felt the want of a "fast stretch" on which they could let out their machines to their heart's content. Thanks to the enterprise of Mr. S. W. Phillpott, a meeting was arranged to take place on part of the new road from Eastham to Ellesmere Port (about eight miles from Birkenhead) —an ideal course of approximately three miles in length.

Mr. S. A. Kelly, road surveyor, a member of the N.M.V.'s, obtained permission to use the road, which at present is not open to the public.

Invitations to take part in the trial were sent to the members of the N.M.V.'s of Liverpool, Southport, and district, the events to be of a purely sporting nature, no entry fees being asked and no prizes given. It was decided to arrange the events on the "knock out" principle—that is, to run the competitors in pairs from the same starting point, ignoring engine capacity, the winners of the heats to meet until all but the winner were eliminated.

RESULTS OF FINALS.

CLASS 1.—C. P. Ellis (2¼ Triumph), walk over.

CLASS 2.—F. W. Mainey (2¾ Douglas) beat H. T. Williams on similar machine. Time, 1 min. 9⅘ secs., about 39 m.p.h. This was the fastest time of the day, being run when the track was in the best condition. Later in the day, when the track became loose and muddy, the riders of the big twin machines did not fancy letting their engines out.

CLASS 3.—F. W. Mainey (2¾ Douglas) beat R. B. Stevenson (3½ Rover). Time, 1 min 13⅗ secs., about 37 m.p.h.

CLASS 4.—F. W. Mainey (2¾ Douglas), beat E. Thomas (3½ Scott). Time, 1 min. 15 secs., about 36 m.p.h.

CLASS 5.—F. A. P. Zacharius (7 Sunbeam) beat F. W. Mainey (2¾ Douglas). Time, 1 min. 11⅘ secs., about 37½ m.p.h. Mr. Zacharius obtained delivery of the Sunbeam only on Christmas morning, and was not accustomed to so heavy a mount.

CLASS 6.—SIDECAR EVENTS UP TO 3½ H.P. R. B. Stevenson (3½ Rover) beat T. Webster (3½ Sunbeam). Time, 1 min. 55 secs., about 23¾ m.p.h.

CLASS 7.—E. Thomas (3½ Scott) beat W. E. Moore (6 Rex). Time, 1 min. 49 secs., about 24¾ m.p.h.

CLASS 8.—ANY POWER. J. Wood (7-9 Harley-Davidson) beat T. Parker on similar machine. Time, 1 min. 24⅘ secs., about 32 m.p.h.

A series of matches was then run off, and provided the most excitement during the afternoon.

Results of Matches.

SOLO EVENTS.

R. B. Stevenson (7 Sunbeam) beat E. Thomas (Scott).

E. Thomas (Scott) beat H. T. Williams (Douglas) by six inches. This was a splendid race: the Scott got away well, and led at the bottom of the dip by 20 yards, then the Douglas came up with a run, only just failing to overhaul the Scott. Time, 1 min. 20 secs., about 34 m.p.h.

R. B. Stevenson (Rover) beat Williams (Douglas). Time, 1 min. 15 secs., 36 m.p.h.

E. Thomas (Scott) beat Zacharius (3 Enfield). Time, 1 min. 20 secs., 33 m.p.h.

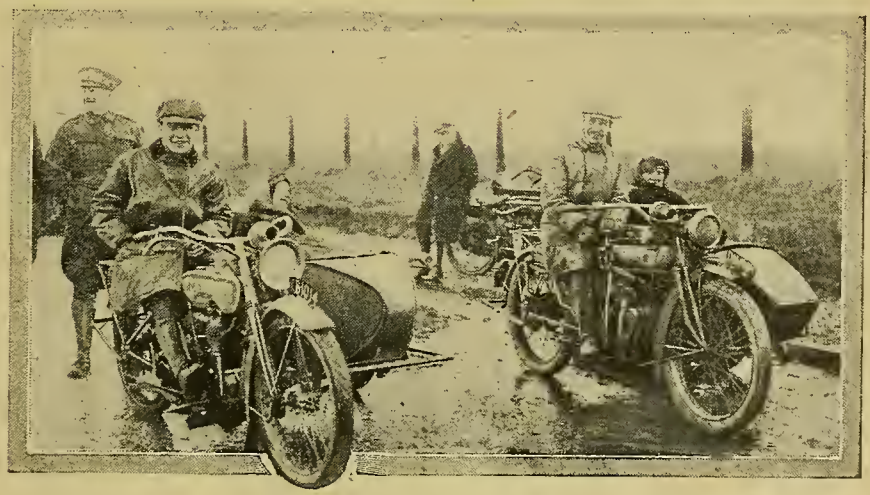
SIDECAR EVENTS.

J. Wood (7-9 Harley-Davidson) and lady passenger beat C. H. Dalmar (7-9 Indian), also lady passenger, by 5 yards. This was a splendidly contested race, as the Indian was travelling the faster at the finish. Time, 1 min. 14⅘ secs., about 31 m.p.h.; fastest sidecar time.

Mr. Parker (Harley-Davidson) beat Mr. Dalmar (Indian).

At about 1 p.m., after the single events had been run off, a move was made to the Ferry Hotel, Eastham, where about fifty members partook of a good lunch, which was paid for out of the section funds. The track being reached again, racing was resumed with sidecar classes, the proceedings terminating at about 4 p.m.

The outstanding features were the speed of Mainey's Douglas and the consistent times of Mr. E. Thomas's Scott.



The most sensational race of the day in the heavy classes was the heat between J. Wood (on a 7 h.p. Harley-Davidson), who won by five yards, and C. H. Dalmar (Powerplus Indian).

CAPE PENINSULA CLUB.

IN spite of the fact that fifty-seven of its members are on active service, the Cape Peninsula Motor Cycle Club seems to have enjoyed a successful season. With a remaining total of two hundred and five members the Social Committee has confined its efforts to organising motor outings for sick and wounded soldiers, and over 1,800 men have been able to enjoy these outings during the year.

LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

A CURIOUS CASE.

Sir,—With my two-stroke New Hudson I have experienced a similar trouble to that of Mr. H. J. Ives *(The Motor Cycle,* December 21st), especially after being out in the rain. I have found running all oil out of the engine and putting in fresh oil very effective. I believe the cause of the trouble is rain being drawn into the cylinder through the air intake.

Weymouth. NOVICE.

Sir,—I believe the trouble Mr. H. J. Ives (2581) has met with in his 2¼ h.p. Levis is entirely due to the release valve, the spring of which obviously requires to be changed for a new and stronger one. It would also be well thoroughly to clean the release valve, valve seat, valve stem, and valve stem guide, and rub them with blacklead before replacing. It would also be well to see that the valve stem itself is true and straight, as it might be slightly bent.

If Mr. Ives carries out the above suggestions I feel confident all will be well again.

MONTAGUE C. WILKINS.

LADY MOTOR CYCLISTS.

Sir,—I have been the happy owner of a Levis lightweight for six months. I have always been interested in motor cycling, and for years before I ever hoped to possess one myself was a keen reader of *The Motor Cycle.* When the war began to make a nurse's work at home twice as heavy I started seriously to contemplate ways and means to obtain something quicker and less tiring than my old friend the push bicycle. Increased work having considerably helped savings, I heard one day of a small Levis for sale which came well within my means, so I went up to see it, and rode home—the first time I had ever been on a motor cycle alone—a distance of about four miles, rather hilly, too, without the least difficulty. Of course, thanks to *The Motor Cycle,* I had a pretty good idea of the workings, and the only small troubles I have had have been through neglecting rules which are laid down by experts, and which the amateur always thinks she can ignore until she finds out differently! Now I take out my Levis about 9.30 a.m., two pushes of my foot and it starts away, and does in a morning what usually took me the whole day. NURSE MARGARET CLARK.

A MOTORIST'S WAR BOOK.

Sir,—I notice in your issue of December 14th you publish a splendid testimony to D.R.'s taken from Mr. Fred Coleman's book, "With Cavalry in 1915." The testimony is no doubt deserving, but I wish to quote one part of the testimony which is liable to convey a wrong impression: "These cyclists generally used a road long after it had been given up as impassable by everyone else, and when they at last abandoned it as too dangerous for use, it was indeed time, in their parlance, to 'give it a miss.'" I notice the village of Potijze is mentioned as an objective of "Macfarline's intrepid motor cyclists."

In defence of a body of men seldom in the limelight, I ask Mr. Coleman, or anyone else who makes such sweeping statements: "How did the motor ambulance drivers continually reach the village and advanced dressing stations, three or four kilometres beyond the village of Potijze, on this same shrapnel-swept road?" In the biggest attack of the period with which Mr. Coleman deals, neither this particular road mentioned nor any other road from Ypres to the trenches was impassable to the boys with the ambulances; neither were they considered impassable to the boys taking up the ammunition and supplies, ample evidence of this being given while the attack lasted by the ever-increasing number of carcases of mules and horses scattered along these same roads, surrounded by wreckage and *débris* of all descriptions, both motor and horse vehicles being represented.

B.E.F., France. FAIR PLAY.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—Never yet have I read anything quite so amusing as the letter from Mr. Michelmore Hitchcock in the issue for December 14th. May I congratulate you on securing it? One passage especially tickles me: "The flat twin, for which there is such a craze just now, is, in my mind" *(sic),* "out of the running as a practical mount wherever economy is of account." Experience has proved that the cylinders of the flat twin wear oval very little, if any, sooner than that of the vertical single. Apparently Mr. Hitchcock does not mind how many tyres and chains (or belts) he wears out so long as his cylinders retain their circular shape for an extra month or so in two or three years.

Might I venture flatly to contradict one statement? He says, "Every rider who has tried the two types knows that there is no sensation of power when riding a twin as compared with a single." This, of course, is absolutely untrue. I have in my time owned and ridden most English makes of both types, besides one or two foreigners (and I have no sort of connection with any of them), so I think I may claim to have had some experience. I can assure Mr. Hitchcock that there is no lack of sensation of power when I touch the throttle of my present twin.

I cannot quite make up my mind as to whether Mr. Hitchcock was being *intentionally* funny or not. While congratulating you on this "article in lighter style," which surely has been crowded out of the Christmas number, I should like to say that I and all my friends greatly appreciated that masterpiece of elegant vituperation from the angry pen of Mr. Osborne de Lissa. Of course, there was nothing ridiculous about *this* letter: it was merely amusing in the way that angry people always are amusing. But we did enjoy it. E. J. L. STRONG.

Sir,—I feel that I cannot possibly let Mr. Michelmore Hitchcock's letter pass without comment. I may say that it caused some amusement among the D.R.'s here (Bishops Stortford), most of whom have been despatch riding for nearly two years, and some more, and all of them were motor cyclists before joining up.

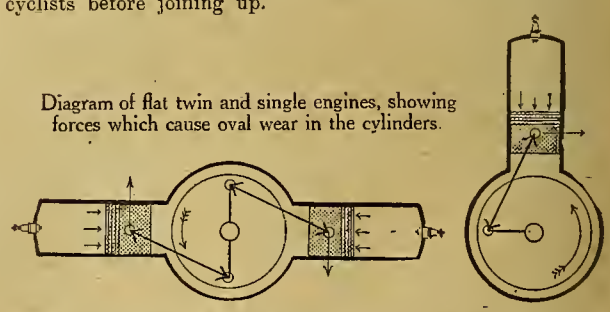


Diagram of flat twin and single engines, showing forces which cause oval wear in the cylinders.

First of all, may I ask Mr. Hitchcock if he has ever ridden on a wet day or on a road that is not quite flat, or ridden a single when it wanted decarbonising? This is when the multi-cylinder scores with its "little patter-patter strokes and feeble explosions." I will not say any more about this

part of the letter, as it is quite obvious to any practical motor cyclist who has ridden both single and multi-cylinder machines (the flat twin for preference).

Now we come to the next part, where he states that the flat twin is not economical, because it wears its cylinders oval. Does not, then, the vertical single wear its cylinder oval? I beg to state that it does, and to practically the same extent.

In the enclosed sketch the arrow heads show the direction of the forces, and the arrows show the direction the engine is turning. To save space I have represented both cylinders of the horizontal twin to be firing at the same time. This is not the case in practice, as they fire at equal intervals. On the exhaust, inlet, and compression strokes the opposite sides of the cylinder receive the piston pressure.

I should also like to ask how it is proposed to lubricate the vertically opposed twin, and what kind of a machine it would prove on the road, with the weight so high in the frame? I should like to hear Mr. Hitchcock's ideas about this. It is my humble opinion that the plug in the bottom cylinder would have a bad time of it in whatever way the engine was lubricated.

As to reliability. Well, ten thousand miles on one machine, in all weathers and under conditions that would turn a civil motor cyclist's hair grey, speak enough on that score. The machine was a Douglas, and I rode it eighteen months and never once had to leave it on the road through a mechanical breakdown. I would not ask for a better machine for its weight and size.

I hope Mr. Hitchcock does not think I intend to be personal, but I think a letter like his shows some types of motor cycle in a wrong light, and might mislead a novice who reads it. He must not think I pretend to be a technical engineer, because I do not, but I have had a little experience on the road, both before and since the war started. I may add that I have no interest in any motor manufacturing concern.

E. KNAPTON, L.-Cpl., Artificer.

Sir,—Having followed with interest several opinions on this topic, I would like to venture my idea.

Within five years of peace being declared, we shall see 2½-3 h.p. singles with two speeds, and sprung front and rear, being sold in thousands at £25 or less simply by standardising and quantity production.

Let us hope we shall do this in Britain without waiting for a Yankee as with cheap four-wheelers. This machine will be so cheap to buy and run that for business purposes there will be a very large demand. As a rider every week-day all the year round to and from business, whatever the weather, after having owned five machines during the last nine years, I consider, for little trouble and expense, the single lightweight is bound to survive.

The splendid behaviour of flat twins will always appeal to long-distance tourists who can afford to buy and maintain them.

My previous experiences from 2¾ h.p. single up to 6 h.p. twin led me six weeks ago to purchase a two-speed four-stroke 2¾ h.p. of British make; I have succeeded with home-made guards in preventing it from plastering me and the carburetter. As you are constantly bringing this important point up in your columns, it is to be hoped makers will attend to it on after-war models.

I do not wear overalls and yet keep clean, but the machine as I bought it would choke up the air gauge on a muddy road in twenty miles by mud flung from the belt, and at anything over 30 m.p.h. mud from the front wheel was all over the rider's legs and on the petrol tank. In spite of the guards fitted, the machine will climb 1 in 6 on a wet day when no rush can be made at it, and also do over 40 on the level, which, after all, is sufficient for the ordinary citizen.

A man, like myself, who makes six journeys per day, *i.e.*, three return journeys to and from meals, cannot waste time putting on and pulling off overalls, much less a doctor who wishes to pay several calls in a day, and who certainly cannot enter a sickroom coated from head to foot with mud.

H. WALKER.

Alexandria, N.B.

AMERICAN BIG TWINS.

Sir,—Like Mr. Bert Houlding, I have followed with great interest your valuable paper, especially on the subject of American machines *versus* English. I ride a Harley-Davidson, not because it is American, but because *no* English machine will give me what I want—that is, *all* the points mentioned in your correspondent's letter—and more, for instance, 28in. wheels and 3in tyres. I *must* have twist grip controls.

I have no object in writing other than that I want to be fair and try to "buck up" our English makers. Like your correspondent, I am English to the backbone, having two sons fighting, and I am on munitions and over age (military), but I use the Harley on special constable work.

R. E. OSBORNE.

Sir,—I have read Mr. Bert Houlding's letter in *The Motor Cycle* of December 28th, and I am more than surprised, after fourteen years' experience, that Mr. Houlding has not discovered a machine of English manufacture to compete against the American in all-round efficiency. Has he ever had the luck to ride and examine such machines as the A.J.S., Sunbeam, etc.? If he has not by chance seen such machines I should say it would be the best for him to do so, and then state where the American so outclasses the English machines of this calibre.

H. A. TOMBLIN.

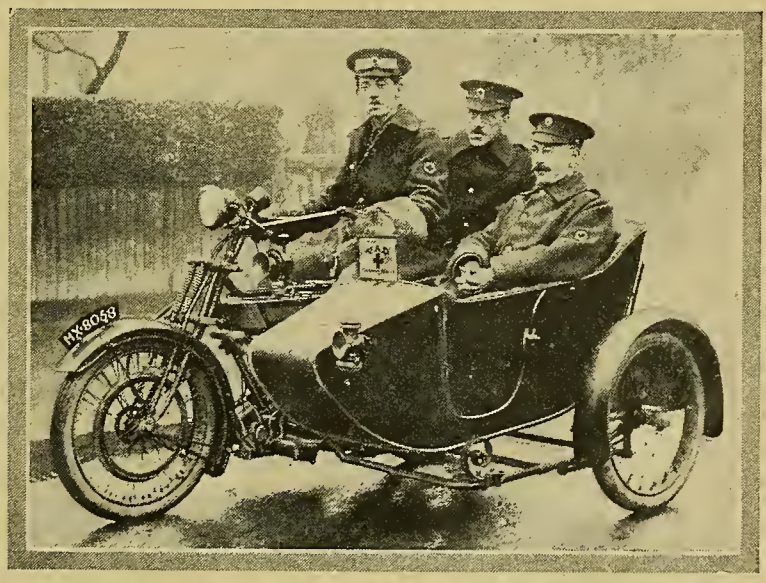
DOING ITS BIT.

Sir,—I am sending you a photograph of my 1916 Royal Enfield combination, which may be seen daily doing its "bit" with the Middlesex Territorial Volunteer Transport (V.A.D.).

Until recently I used a 4 h.p. New Hudson and sidecar, but the frequency with which it is necessary to carry three up made the extra horse-power very desirable, hence my decision to buy the Enfield. This is one of *the only two sidecars in Middlesex* which are authorised to carry the Motor Transport plate (seen on sidecar), and even now, as you point out in a recent issue, I may not take wounded on board when on convoy work.

It is a curious thing that sidecars are used for this express purpose in some parts, but here I have several times seen slightly wounded cases standing in a queue waiting for the cars to return from the hospital for them, but the sidecars have to stand idle. Our detachment (Middlesex 25th, Muswell Hill) at present has vacancies for bearers (not motorists) and, if any of your readers living near would like to share in this interesting work, I shall be pleased to put them in touch.

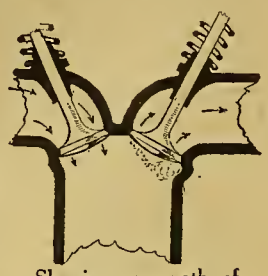
ARCHIE HANDFORD.



Members of the Red Cross Voluntary Aid Detachment, Transport Service, on a 6 h.p. Enfield sidecar. (See Mr. A. Handford's letter.)

THE FLAT TWIN AT THE BAR.

Sir,—With regard to Mr. Bradshaw's recent article on the flat twin, I see the case against this engine was very ably stated by Mr. Osborne de Lissa in your issue of December 14th. The shading in Mr. Bradshaw's original sketches indicates what he terms a "hot side" to the overhead valve engine, but he does not, apparently, consider his own design gets hot anywhere. He also shows what a perfect run in and out the gases have on his engine, but apparently forgets they burn in the cylinder; and do not stream straight through the inlet and out of the exhaust. The bend in the pipe of the o.h.v. engine would cause practically no obstruction—the gases would merely pile up there ready for the next inlet. The gas passages are much freer in the o.h.v. engine, without the disadvantage of a pocket.



Showing easy path of gas adopted in many aero engines. (See letter "A.A.S.")

However, surely a clever designer of Mr. Bradshaw's ability must realise that the parallel arrangement of the valves as shown for the o.h.v. engine is not the best, placing, as it does, a very definite limit on the valve diameter. In the aero world, practically every engine with any pretence to efficiency has valves arranged as in the enclosed sketch. The easy path of the gases is at once apparent, as is also the fact that the valves and ports are limited in size only by the designer. This design is obviously better adapted to the single-cylinder engine, and, practically, we mount the hottest part of the cylinder in a position where, if distortion does occur, it does not affect the cylinder bore. Lest critics arise, I hasten to add this valve arrangement presents no difficulty of operation.

Bournbrook. A.A.S.

Sir,—I have read Mr. Osborne de Lissa's remarks with considerable care, but as they appear to contain very little technical or practical information for the motor cyclist, and as I am much more interested in helpful discussion than in replying to unpremeditated personal attacks, I am afraid I must ignore many of his remarks.

There are, however, one or two details that merit attention, the first being his preference for a hot side to a hot top, because, as he says, with the hot side the piston and the oil which it brings up can conduct the heat away—where to, he does not say. I will leave the motor cycling public to judge for itself whether it wants the lubricating oil to serve the double purpose of lubricating the engine as well as cooling the cylinder, or whether it would prefer the oil to be kept at as low a temperature as possible, so as still to retain its lubricating properties. Personally, I much prefer the working parts to be kept as cool as possible, and to transfer the heat to some other part that does not matter, and with this I have no doubt the majority will agree.

With regard to plug electrodes dropping into the cylinder, and wonderful drawings that were to astonish the world, I have nothing to reply, as in the case of the former the A.B.C. engine is very easy on plugs, and I have no knowledge of the latter.

If Mr. de Lissa, instead of referring so much to the supplying of racing engines for commercial purposes, had suggested wherein lie the peculiarities of the A.B.C. that make it a racing engine, he might have brought to light some particulars worthy of discussion.

As a matter of fact, it is perfectly obvious, even to the casual eye, that the aims in the A.B.C. design are improved cooling, absence of vibration, exceptionally long life, perfect smoothness, capacity for continuous heavy duty, and correct and regular oiling. These features stand out in every single important departure from orthodox practice that can be found in the design, and surely these are essential to the touring motor cycle of the future.

Perhaps the addition of rear springing, two separate cushion drives, four-speed gear box, leaf front springing, etc., are further points that made Mr. de Lissa think the A.B.C. is a racing machine.

If Mr. de Lissa cannot see the advantage in fitting a four-speed gear box, I would advise him to try a comparison of such with a three-speed gear box, and I would also remind him that in car design there were originally many who belittled the four-speed gear box, until they evolved an engine that was capable of taking advantage of the extra ratio, and it has rapidly become adopted in most cars.

The A.B.C. does not *necessitate* a four-speed gear box; but the engine has peculiar qualities which make the machine much more efficient with such fitted, and high efficiency is our chief aim.

Mr. de Lissa's innuendoes regarding wear in actuating rods, rendering three, and in some cases only two, speeds obtainable, are quite sufficient to show that he has never observed the ordinary orthodox car practice of the A.B.C. design.

With regard to cast iron suitable for mangles and bedsteads, I confess to inferior knowledge of the subject, as my time has been devoted to materials of high class.

Whilst on this matter, I would like to clear up an impression that the A.B.C. is not being produced on account of the war. I should be pleased to show Mr. de Lissa, any week he cares to make a visit to our works, at least 100 A.B.C. engines in the course of construction and testing.

GRANVILLE E. BRADSHAW.

AN UNUSUAL JET.

Sir,—In a letter from the Rev. G. T. Basden, Awka, Nigeria, West Africa, occurs the following, which we thought would interest your readers (letter dated November 10th, 1916):

"My only neighbour here came in a week or two ago with his machine. It is a two-stroke Junior Triumph. His carburetter had broken down. The collar holding the jet tube in position had broken in two. That had given way, and he lost the jet tube. I worked at it, and faked up a jet out of a rusty 2in. wire nail, and strapped the part together with wire. He is now getting thirty miles more per gallon when running. I doubt whether there is another machine in the wide world fitted with an old nail as a jet. What do you think? He has sent for another jet, but states that he will not change the present profitable arrangement."

T. BAKER AND SONS.

F. R. MULLIN.

A NEW PETROL.

Possibilities of Government Oilfields and Control over Petrol Interests.

THE new petrol, of which we spoke vaguely last week, is to be known as B.P. spirit. It was available from Monday last, and will be handled by the British Petroleum Co., who, as everyone knows, until quite recently were the factors of the well-known Shell motor spirit. The company has handed over its original stock of tanks, lorries, cans, etc., and until the completion of its new bulk storages and plant, which are in the course of construction, the Anglo-American Oil Co., Ltd., is to store the new B.P. spirit for the British Petroleum Co. The B.P. spirit will be sold in three grades as follow:

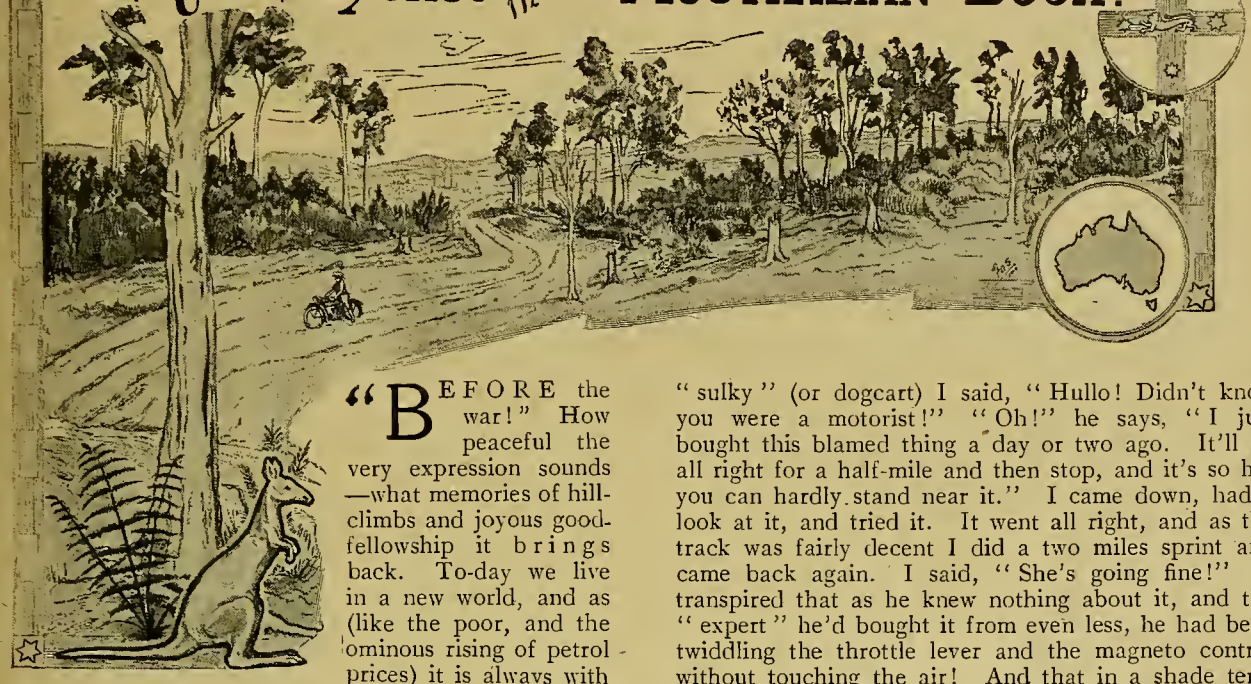
No. 1 in straw coloured tins and priced at 2s. 10d. per gallon.

No. 2 in half straw and blue tins at 2s. 9d.

No. 3 in blue tins at 2s. 8d.

The whole of the share capital of the British Petroleum Co. is vested in the Public Trustee, while its affairs are to be controlled by directors approved and in four cases appointed by the Board of Trade. These facts, coupled with the fact that the Board of Trade made the arrangements for the company to commence the sale and distribution by January 1st, cause one to pause and ponder. It is quite conceivable that at an early date the British Government may acquire and exploit oilfields, and so rid this essential industry of the foreign interests which have existed hitherto.

A Motor Cyclist in the Australian Bush.



"BEFORE the war!" How peaceful the very expression sounds—what memories of hill-climbs and joyous good-fellowship it brings back. To-day we live in a new world, and as (like the poor, and the ominous rising of petrol prices) it is always with us, the reader may pardon a few reminiscences of that old and gone world.

"Before the war" I was spending a quiet existence in the Australian bush. Our business was in a small township in the Riverina district of New South Wales. We were in the store-keeping line, and sold everything from a Ford to a Massey-Harris binder! The population was about five hundred, but the little town served a huge area. I had been for years a motorist in the Old Country. In Melbourne I had done a fair amount of motor cycling during a short stay, but my introduction to an average bush road took place a week or so after my arrival in the "back-blocks." It was on an "Amurrican" car with a "live" Amurrican driver—and in the dark. I was never nervous, but I felt "real blue" that night. The road lay through fairly dense bush and the track was just wide enough for the car. I think that for every yard we were on the track we were two in the air. The twistings and turnings, and the head lights beaming along on the dust ahead, kept one's heart in one's mouth all the while, and the vision of a crash ever imminent. We got home O.K., but my sleep that night was a tangle of Fords climbing trees to find that squirrel, of Rolls-Royces doing the Gaby glide in a forest, and of mo-bikes holding a bouncing competition! After that I gave up all thought of motor cycling! One day, however, whilst driving, I saw some distance away a "'bus" propped up against the fence of a wheat paddock. The "'bus" owner was sitting on the fence, and as we came nearer I recognised the blissful countenance of a friend, a young Methodist parson. The "hot air"—from the bicycle—was percolating heavenwards. The parson was dusty, hot, and perspiring, and the look on his face was akin to that so aptly described in *Punch* as "the profane silence." From the "sulky" (or dogcart) I said, "Hullo! Didn't know you were a motorist!" "Oh!" he says, "I just bought this blamed thing a day or two ago. It'll go all right for a half-mile and then stop, and it's so hot you can hardly stand near it." I came down, had a look at it, and tried it. It went all right, and as the track was fairly decent I did a two miles sprint and came back again. I said, "She's going fine!" It transpired that as he knew nothing about it, and the "expert" he'd bought it from even less, he had been twiddling the throttle lever and the magneto control without touching the air! And that in a shade temperature of over 100°! (Q.E.D. Given a 2½ h.p. two-stroke, under similar conditions. State temperature of surrounding district!)

A First Taste.

But that short run sealed my fate. I had tasted of the wine and it had gone to my head! Soon afterwards I picked up a single-geared free-engined Bradbury, and persuaded a pal to go in for a Triumph. Then the fun commenced. We used our machines mostly for week-ends at the river Murrumbidgee, which was about twenty miles away. Sometimes we stayed at the house of a friend near the river. At other times we "carried our swag" (*i.e.*, blankets, etc.)—not as the real "swaggie," with his billy-can in his hand and his swag upon his back—but with the "swag" cushioning the carriers and the cooking utensils, etc., slung around us. On these occasions we camped out by the river, got our camp fire and our "flip-jack" expert going, lit our cigarettes, set our lines for Murrumbidgee "whales"—a foot long—and had a lazy, happy time. Between bathing, shooting with a pea-rifle, and talking "motors," Sunday night came all too soon. It says much for our good old British mounts that for nearly a year we ran there regularly without any serious mishap, sometimes with passengers (the aforementioned "expert" being one), and over ruts, dust-traps, and pot-holes that would have made the pre-war racing "K-nut" throw himself in the river. I do not think that any of the home riders (and certainly not the designers!) can form any conception of these tracks. The colour of the soil is reddish, and one moved along in a column of brick-red dust. Even were the surface good, the constant dodging of trees, big stumps, and projecting roots, added to the zigzaggedness of the route, made speed

A Motor Cyclist in the Australian Bush.—

impossible. And then there were huge pot-holes, sand drifts, ruts, a blazing sun, and aching arms and bones. To parody a well-known poem—

"So many tracks that wind and wind,
But with no chance of doing a 'blind.'
Or any burst of speed!"

A Snake causes a Spill.

Coming home one Monday morning my chum ran over a black snake which got mixed up with his front wheel and got smashed. The bicycle was running in some heavy dust and it came a beautiful croppér. The only damage was a pair of bent handle-bars.

We had, of course, on such tracks many minor spills, but as one could not drive fast we got off with small damage. Rabbits were there by the thousand, and at night we bowled many over. We had some good long runs to places like Wagga-Wagga, the Rock, Junee, and Coolamon. My petrol consumption worked out about 85 m.p.g., and in the matter of lubrication I got by far the best results from Price's Huile de Luxe.

Weather Conditions.

The bush is wonderfully still and silent. Except when accompanying rain and duststorms, there is never any wind. In the cool winter evenings conditions were perfect for running. Practically the whole year round there was sunshine, and in the middle of winter I have seen the temperature over 80° in the shade. It was gloriously healthy. But when the rain came it usually rained a year's supply in three days. We got caught in one rainstorm, and were, after five minutes of it, going to abandon our machines, when we saw a "cocky's" (farmer's) house, and pushed them there. We did not get away till midday, and the tracks were a mass of sticky clay. Oh! for these wide mudguards! We stopped every half-mile or so to clear away the conglomeration of Australia that blocked the wheels—and cursed volubly! Did space permit I could tell of summer duststorms, when Egyptian darkness fell upon us at noonday, and one became as Lot's wife—a pillar of dust (not salt!); of days when the bush fires raged and the shade temperature soared to 120°, and when not only the engines sweltered but the handle-bars got excessively hot.

The Overseas Market.

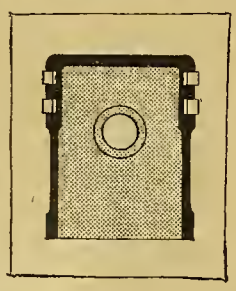
When will our manufacturers awaken to the possibilities of the Colonial market? In Australia nearly all the working men can afford a machine. I noticed before I left that large numbers of the shearers, who go from station to station, had given up their horses and taken to motor bicycles—mostly Triumphs. From what I hear I believe that now the American machines are replacing them all. It will pay our manufacturers to lower considerably the prices charged in the Colonies, sell at a fair margin of profit, oust the American competitors from the field, and, as the Scotch saying has it, "Keep our own fish guts for our own sea-maws!"

In conclusion, I should like to see all designers of Colonial models have six months running over bush roads on an ordinary British machine. We would then see the spring frames, wide mudguards, high clearances, split-pinned nuts, and general accessibility that the soul of the Colonial rider longeth after. With attention to the price question I venture to prophesy that, as in the days before the war, so shall the days after the war be, and British material, British finish, and British reliability rule in the motor cycle markets of our mighty Empire. McK.

INCREASING SPEED.

A Reader's Suggestions for Improving the Speed of his Motor Cycle, and a Warning.

MR. ROBT. BAKER WHITTICK writes: "I find that more speed can be obtained from a Triumph by fitting a fairly large jet and giving the carburetter plenty of air. Another good scheme is to turn down the part of the carburetter to which the float chamber is attached, and so raise the jet until it comes almost in a line with the air inlet.



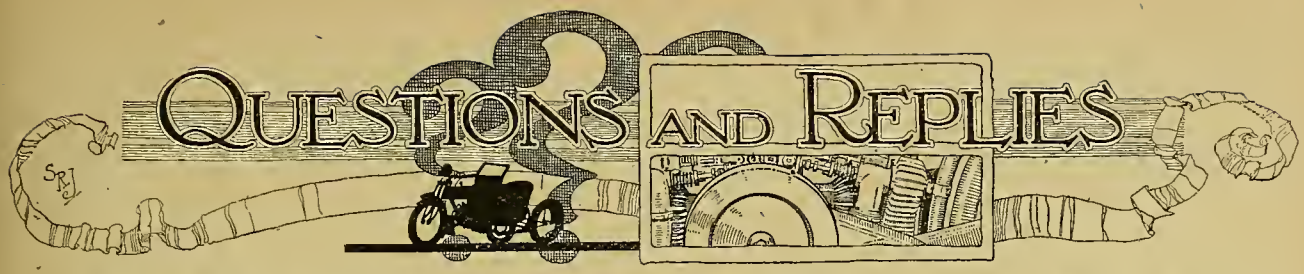
"An appreciable difference is also made by fitting stronger valve springs, and by making the present Triumph cut-out open to four holes instead of two. The back pressure in the engine is considerably reduced without causing very much more noise. Yet another tip for increased speed is to reduce the bearing surface of the piston by grinding the skirt, as shown in the sketch."

Our correspondent's ideas are quite sound, but a word of caution is required on one or two points. The carburetter is a delicate instrument and is easily put out of order. When cut down as suggested, it is clear that if the alteration does not prove a success it will be impossible to restore it to its original form.

His next idea is "stronger valve springs." This is another point in which discretion is required, for, although weak valve springs cause lack of speed and power, the effect of fitting over-strong springs may result in broken valves, broken tappet rocker rollers and studs, in addition to causing loss of efficiency owing to the power required to raise the valve against so strong a spring. It is therefore necessary to strike a happy medium.

His third suggestion is to open the cut-out holes in order to reduce the back pressure. Of course, this is a "sound" idea, and would undoubtedly have the desired effect, but with the increased speed and power the noise of the exhaust is also increased, and is likely to attract the unwelcome attentions of the police. The most efficient way of dealing with this problem is to fit a good-sized tail pipe to the silencer, as is done on most of the latest models. In this way the back pressure is reduced, while the noise is not unduly increased.

The fourth suggestion is also quite a good one, but here again a word of warning is necessary. Great care is needed to see that there is sufficient metal to allow for the recess to be turned in the piston. If the metal is reduced too much a fracture is very liable to occur.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Motor Cycle Licences.

Is it legal for a motor cyclist holding a driving licence to drive another man's motor cycle, the owner having paid Inland Revenue tax and registration fee?—J.G.M.

Yes; provided the machine is registered and the tax paid by the owner, anyone may use the machine if he hold a driving licence.

Gear for Twin.

In reading the report of a run to the Welsh Coast, in your issue of November 16th, I note that you state the top gear is $5\frac{3}{4}$ to 1.

Now, I should like to ask you is that gear too low for a 6-8 h.p. twin 1913 Rex de luxe, and will it affect the internal wear of parts? Speed never exceeds twenty miles per hour. I do plenty of hill work: single figure gradients.—T.J.J.

We would certainly say that $5\frac{3}{4}$ to 1 is too low a gear.

If a high average is attempted with such a low gear, excessive wear is bound to result.

Valve Timing.

I shall be obliged if you will tell me whether this timing would have a tendency to cause overheating and high petrol consumption: If the exhaust valve starts to open $\frac{9}{16}$in. from the bottom of the stroke, is fully open about $\frac{3}{16}$in. past the bottom, and quite closed just past the top. The inlet starts to open about $\frac{5}{16}$in. before reaching the top, fully open $\frac{1}{4}$in. past the top, and quite closed about $\frac{3}{16}$in. past the bottom.—A.M.

The timing of your engine is rather exaggerated. Of course, makers' timings vary considerably, and it is possible that yours is the most suitable for that type of engine. We would suggest the following timing as being more suitable for most engines for ordinary touring: Exhaust valve to close on top dead centre slightly after rather than before the dead top; inlet valve to open immediately the exhaust has actually closed, and should remain open until the crank reaches the bottom dead centre, or very slightly over, say, until the piston has risen 1 mm. on the compression stroke. The opening of the exhaust valve can be left to the cam design. As a rule, the opening point will be found to be about one-seventh the length of the piston stroke from the bottom of the firing stroke.

Twin Lubrication.

I have been troubled with an overheated front cylinder on my 5-6 h.p. V twin motor cycle. It has the usual hand oil pump on the side. Would you recommend the petroil system to help to lubricate front cylinder?—J.M.G.

Make sure that the baffles of the crank case are removed from the orifice of the front cylinder, and also that the piston rings are not too tight a fit. If these two points are in order, it might be advantageous if you fit a bypass to the oil feed pipe and lead a small supply direct to the front cylinder. To do this, drill a hole near the bottom of the stroke in such a position that when the piston is at its lowest point the hole registers roughly with the centre of the piston. Fit in the hole a union, and connect up the auxiliary oil pipe. The additional petroil system would supply extra oil to rear cylinder also, which is undesirable. It is further inclined to make the whole machine oily.

In submitting to the Editor articles, photographs, or drawings, contributors are asked to mention whether the illustrations are exclusive, and further to enclose a stamped addressed envelope for return of unaccepted contributions

Taking Down an Engine.

What tools are necessary to enable me to take down my motor cycle engine? My machine is a 1909 $3\frac{1}{2}$ h.p. Triumph, and I find that all the nuts are too tight to be moved with the ordinary tools. I find I cannot remove the cylinder without removing the engine from the frame, and the holding-on nuts are very tight. Which is the best way to remove the valve caps?—G.A.

Ordinary engine spanners, such as are supplied by the company, should suffice. If these are not sufficient, the only thing you can do is to employ brute force and remove the nuts with the aid of a cold chisel and a hammer, replacing them afterwards with new ones. When you have removed the nuts from the holding-down bolts, we think that if you take the cylinder in the left hand, hold the engine pulley with the right, and work round the piston to its lowest point, or if you tip the cylinder forward, at the same time turning the pulley so as to move the piston to its lowest point, you will be able to remove the cylinder without taking the engine out of the frame. The best way to remove the valve caps is first of all to squirt paraffin round the edges overnight, and then get a spanner fitting them exactly, and either a lead hammer or a heavy mallet, and hit smartly with a series of good strong blows.

Who is Liable? Driver or Owner?

Is it possible for anyone to be summoned for riding a motor cycle which belongs to someone else, and is registered in that person's name, and which has only been lent to the driver?—S.P.

Yes, a man can be summoned for any offence under the Motor Car Act, even if not riding his own machine, but cannot be fined for driving the machine because it is not registered in his own name. If, however, the owner of the machine has not registered and paid the necessary taxes, the rider of the machine is then liable for riding an unregistered motor, whether it is his own machine or not.

Weak Magnets.

My Bosch magneto does not give a very strong spark; do you think it wants remagnetising, and also do you consider I could do it? I have a 50 volt D.C. electric plant for lighting my premises. I believe the remagnetising is a simple job if one knows how to set to work on it.—ATMOS.

The weak spark of your magneto may not necessarily be due to weak magnets You can usually tell whether they are in order by turning the armature shaft round, and, if a fairly strong resistance is felt, then you will know the magnets are all right. Overhaul the magneto thoroughly to make sure all other points are in order, the carbon brush and slip ring quite clean, contacts clean and making and breaking contact properly, and so on. We would not advise you to try remagnetising the magnets yourself. With the proper appliances it is a very simple job, but unless properly done the result may be worse than the original trouble. The usual method of remagnetising is by the use of an electro magnet. The magnet to be treated is placed end to end with the electro magnet—opposite poles together. The current is then switched on and off, and the magnet very soon becomes recharged, so to speak, with magnetism. Different makers have different methods, however.

Illuminating the Number Plate.

I have been a reader of your most interesting paper for just on six years, and I have obtained many useful hints from it. I should be extremely obliged if you would tell me if the rear number plate of a solo motor cycle has to be illuminated at night.—W.P.H.G.

Only one number plate on a motor cycle need be illuminated. This may be either the back or front number plate.

Scored Cylinder.

I bought a 1912 Rex 6 h.p. and sidecar last year. On taking it down I found one of the gudgeon pins had worked loose and scored the cylinder from the top to the bottom. I am afraid it has gone too far for reboring, as it has quite a groove in the cylinder. Would it be best to put it back as it was and let it run itself out or have it rebored? Would there be great loss of compression?—E.P.

We should advise you to fix the gudgeon pin securely in its place. The effect on compression will depend very much upon the depth of the score. You can find this out by testing. It may not make much difference to the running of the engine. Reboring and fitting a new piston is the only real cure.

READERS' REPLIES.

Acetylene Lighting Troubles.

Perhaps the following tips will be of use to "J.S.P." (Dec. 14th): If the small rear light burner is removed and a small bicycle burner put on instead, vibration will not shake it out, as a slightly larger supply of gas is used, and at the same time the difference to the front light is hardly noticeable. To save rubber tubing, I use the outer member of the Bowden cable covered with ebonite and connect with small pieces of rubber tubing. This has answered my purpose for over twelve months without trouble.—S.P.T.

Misfiring in a Twin.

In your issue of October 12th there is a query by "H.C." His front cylinder does not fire till the engine is raced. I had similar trouble with my A.J.S.—bad misfiring, except at high speeds. I looked for all you suggest—air leaks in induction pipe, valves seating properly, valve springs in good order, changed plugs, platinum points clean, and breaking properly. Result, nil. Lastly, I checked over tappet clearance, and found in the front cylinder that I had adjusted up too closely, probably causing slight overlap. I slackened off till the magneto gauge would easily slip in between the tappet and the valve stem, and misfiring at once ceased. The machine now runs perfectly again.—(Rev.) A. M. Walmsley, Kandy, Ceylon.

Broken Gear Spindles.

In the issue of December 14th you reply to "G.H." *re* Scott gear. I may be able to throw some light on the subject. I do not know if the 1912 edition is different from the 1914, but in the latter there is no lock nut to fix the gearshaft cones, or, as it is called in the list of parts, gear hollow spindle, which has a long screw on the gear pedal end and a short screw with collar on the opposite end. To describe how two of these are fitted on different machines: First put into place with balls and cones and with the short screw cone screwed up to the shoulder, screw up the right-hand cone on the long screw, and then measure from the end of the spindle to the back of the cone. (I am presuming the cones tightened on the balls before they tightened against the ends of the threads.) Now take out the spindle and screw the cones up tightly to the end of the thread and measure again. The difference represents the thickness of the washer to be placed between the left-hand cone and the collar on the spindle; if, however, the cones tighten on the spindle before the bearing is tight enough, *i.e.*, there is still slackness in the bearing, the end of the spindle at the long screw end where the cone abuts must be turned down, a little at a time, till the bearing is in adjustment. In both the spindles I fitted it was a case of putting in washers to prevent the cones screwing up too tightly. It requires a bit of patience to get them just right, but unless they are the long screw cone will tighten up in running and cause the trouble experienced by your correspondent. Where I have spoken of right or left-hand cones I mean as viewed when seated on the machine. Thus the right-hand cone is that on the long screw, and the left-hand cone that on the short screw end of the spindle.—D. G. Taylor.

RECOMMENDED ROUTES.

Aldershot to Berkhamsted.—P.A.L.

Aldershot, Farnborough, Bagshot, Ascot, Windsor, Beaconsfield, Chesham, Berkhamsted. Approximately forty-five miles.

Llantrisant to Kidderminster.—J.W.

Llantrisant, Pontypridd, Quaker's Yard, Nelson, Newbridge, Pontypool, Usk, Monmouth, Ross, Ledbury, Malvern, Worcester, Kidderminster.

Chippenham to Dorchester.—R.N.B.

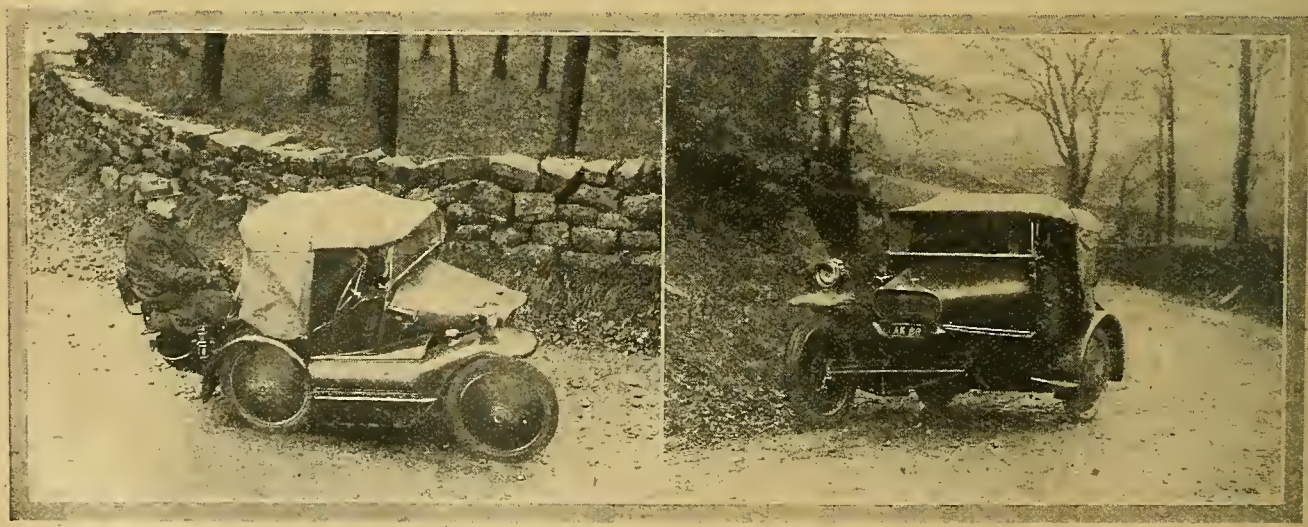
Chippenham, Melksham, Westbury, Warminster, Shaftesbury, Blandford, Whitchurch, Puddletown, Dorchester. Approximately 96 miles.

Staines to Cardiff via Gloucester.—J.W.R.

Staines, Windsor, Slough, Maidenhead, Reading, Wantage, Farringdon, Cirencester, down Birdlip (good road), Gloucester, Newnham, Chepstow, Newport, Cardiff.

London to Newtown.—G.H.

London, Edgware, Rickmansworth, Watford, Berkhamsted, Tring, Aylesbury, Bicester, Hopcrofts Holt, Chipping Norton, Moreton-in-the-Marsh, Broadway, Pershore, Worcester, Tenbury, Ludlow, Bishop's Castle, Brompton, Kerry, Newtown. Approximately 193 miles.

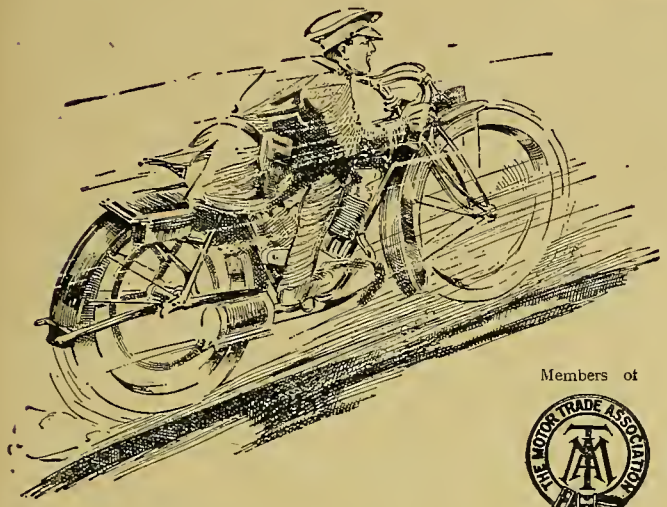


TESTING THE SCOTT SOCIABLE AMONG YORKSHIRE HILLS AND DALES (see pages 4, 5 and 6.)

Very complete protection from the weather is provided by the hood, screen, and side curtains for the driver and passenger. This was much appreciated midst the rainstorms when crossing the hills and dales of Yorkshire The dickey seat is good—particularly in fine weather!

A.V. Magnetos

BRITISH THROUGHOUT



"The Magneto that is not too proud to spark."—*The Motor Cycle.*

WILL positively START UP at a walk; exceptionally lively at picking up; never a sign of misfiring at high or low speeds; miles per hour faster than other magnetos; totally enclosed; dustproof and waterproof.

MOTOR CYCLES.

SPECIAL NOTICE.

The Ministry of Munitions has given us permit to supply any motors, erected or assembled up to the 15th February, 1917. If Agents, therefore, are desirous of securing motors which we have coming through the works they could be delivered before that date; after that date we expect no more motors can be supplied for the English market.

We have in stock, and in course of construction, the following motors, which we can deliver before the expiration of the date of the Government permit.

MODEL B, 2¾ h.p. Two-stroke.

All latest fitments for 1917.	Cash Price
Single gear	£28 17 6
Two-speed gear	£35 16 6
Two-speed gear, kick starter, and free engine clutch	£39 5 6

MODEL C, 2½ h.p. J.A.P. Four-stroke.

	Cash Price
Single gear	£31 5 0
Two-speed gear	£38 2 6
Two-speed gear, kick starter, and free engine clutch	£41 12 6

MODEL D, 4 h.p. Four-stroke.

	Cash Price
Solo single gear	£41 12 6
With two-speed chain and belt or double chain drive	£53 2 6
With three-speed ditto	£55 10 6
With two-speed as above, with coach-built sidecar, complete	£65 17 6
With three-speed ditto	£68 5 0

Telephone No. 735. MANUFACTURED BY Telegrams—"Engineering."

THE WULFRUNA ENGINEERING COMPANY, LIMITED,
GREAT BRICKKILN STREET, WOLVERHAMPTON.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ____ & Co. ILIFFE & SONS Ltd., and crossed ____

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

☞DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

A.J.S.

A.J.S. Spares, prompt delivery.—Cyril Williams, A.J.S. Agent, Chapel Ash Depot, Wolverhampton. [X3491

A.J.S., 1915, 2¾h.p., accessories, perfect; £40; exchange higher power.—Pigot-Disney, E. Molesey, Surrey. [6763

WAUCHOPE'S, 9, SHOE LANE, FLEET ST., LONDON.

'Phone: 5777 Holborn. Wires: "Opificer, London."

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

1916 Douglas, 2¾h.p., W.D. model, new August, done 500-600 miles, lamps, tools, and Stewart mechanical horn; £48.—Oxford Villas, Laleham Rd., Shepperton. [X3839

GIRDER Frame Douglas, suitable for either lady or gentleman, 2¾h.p., 2 speeds, clutch, footboards, excellent condition throughout; £33.—Alder, 16, East Park Rd., Harrogate. [6657

1914 2¾h.p. T.T. Douglas, 2-speed, new Dunlops, B170 saddle, 2 Lucas lamp sets, horn, Stewart speedometer, excellent condition; £38/10.—Robinson's Garage, Green St., Cambridge. [6714

DOUGLAS, 1916, 4h.p., 3 speeds, kick starter, tyres unpunctured, run 1,000 miles, perfect mechanical condition; expert examination, P. and H. lamps, tools, etc.; £60.—Royal Hotel, Capel Curig. [X3831

DOUGLAS Combination, 4h.p., late 1915, absolutely unscratched, 3 speeds, clutch, kick start, Douglas coach sidecar, speedometer, lamps, Lucas horn, spare tyre; £70.—Pike, Thoroton St., Nottingham. [X3834

DOUGLAS, practically new, War Office, 2-speed, T.T. all-weather model, all grey, fully equipped, smartest on road, perfect; trial; £54, or with cash for 1916 twin combination.—A.E., 23, Market Place, Kingston, S.W. [6698

Enfield.

COLMORE Depot, 31, Colmore Row, Birmingham, for immediate delivery of Enfields. [0801

ENFIELD 1916 6h.p. Combination, lamp, horn, new 2 months ago; £85.—Lamb's, below.

ENFIELD 1916 6h.p. Combination, Lucas lamps, Stewart speedometer, horn, mileage slightly over 1,000; £84; Enfield commercial chassis, with quite new box, 12 gns.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. Tels.: Walthamstow 169 and Hornsey 1956. [6646

ENFIELD 1914½ 6h.p. Combination, hood, screen, splendid condition; £58.—29, St. Leonard's St., Bow, E. [6575

1913 Enfield 6h.p. Combination, all accessories; £45.—Smith, 16, Haverstock Hill, opposite Chalk Farm Tube Station. [6603

MOTOR CYCLES FOR SALE.

Enfield.

1916 3h.p. Enfield, mileage 2,000, faultless, speedometer, horn, lamps, shock springs; bargain, £49.—32, Steade Rd., Sheffield. [X3843

RIDER TROWARD, 78, High St., Hampstead.—1916 Enfield combination, mileage 600, new condition, 3 lamps; cost £110, 68 gns. [6742

1916 Enfield Combination, ridden once, unscratched, perfect throughout; 79 gns.; cheaper machine part.—245, Hammersmith Rd., London, W. [6709

ROYAL Enfield, 1915, 2-stroke, exceptional condition, large black P. and H. head light set, rear light, horn, all tools, only run few miles; £35.—Kitcat, 6, Parade, Cowes. [6608

ENFIELD Combinations.—New models in stock; 6h.p., 2-speed, £94/10; cash, exchange, or deferred payment terms.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C. [0552

ENFIELD Combination, 90 gns.; 3h.p. twin, £57/10; 2-speed, 2-stroke, £45; delivery from stock.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter, and Tavistock Rd., Plymouth. [0838

1916 3h.p. Enfield, 2-speed, kick start, Millers head and Lucas rear lamps, mechanical horn, Thompson-Bennett mag., ridden 500 miles only; bargain, £42/10.—Robinson's Garage, Green St., Cambridge. [6715

1917 Enfield, 3h.p., 2 speeds, complete with lamps, horn, and numbers, only ridden 50 miles; cost with accessories £63; officer ordered abroad; sacrifice £55; approval.—Foulor, 36, Clarence St., Kingston. [X3872

ENFIELD Combination, 1916, perfect condition, hood, luggage carrier, spare covers and tubes, lamps, horn, speedometer, many spare parts and tools; 67 gns.—Crawley Bros., 45, Hockerill St., Bishop's Stortford. [6633

BIRMINGHAM Enfield Agent, P. J. Evans, 87-91, John Bright St.—Immediate delivery all 1917 models, including lighting set combination, special 8h.p. with hood and screen, and standard 6h.p. combination, also 3h.p. standard and sporting models, and 2½h.p. 2-stroke; prices from 42 gns. [X3764

ENFIELD 1916 6h.p. Combination, Lucas dynamo lighting, electric and bulb horns, screen, apron, spare tyre and inner tube, spare chain and valve, inspection lamp, luggage grid, Pillion seat, mirror, Watford speedometer, new May last, done 2,720 miles; £90, no offers.—51, Park St., Birmingham. [X3756

ENFIELD, just arrived, dynamo outfit, 6h.p., hood and screen, £115/15; also 6h.p. 1917 standard combination, hood and screen, £100; 3h.p. solo models, T.T., touring, £57/15; actually in stock; good prices offered for second-hand up-to-date machines in part exchange; deferred terms if desired.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [6643

Excelsior.

EXCELSIOR, 1916, 7h.p., 3-speed, and coach sidecar, used for demonstration; £69/10, cash bargain.—Motor Exchange, Horton St., Halifax. [6666

AMERICAN Excelsior, Model de Luxe, 4 electric lamps, speedometer, Canoelet sidecar, wind screen, hood, bought week ago; owner ordered Front; bargain, £90.—97, Divinity Rd., Oxford. [X3801

Fafnir.

FAFNIR, in splendid condition, new mag.; £22/10, or nearest offer.—Crawley Bros., 45, Hockerill St., Bishop's Stortford. [6632

F.N.

F.N., 1914, 2½h.p., 2-speed, clutch, as new; £28; exchanges entertained.—C., Holly Lodge, Radnage, near Stokenchurch, Bucks. [6609

3½h.p. F.N., 4 cyls., recently overhauled and re-enamelled, excellent running order; £20, or near offer.—Box 591, c/o *The Motor Cycle.* [X3695

2¾h.p. F.N., Bosch mag., clutch, splendid condition, £10; also 1912 F.N., 4-cyl., clutch, £15.—Smith, 16, Haverstock Hill, opposite Chalk Farm Tube Station. [6603

Harley-Davidson.

J. A. STACEY, 12, Ecclesall Rd., Sheffield, for immediate delivery of Harley-Davidsons. Spares, 24 hours' service. [6244

1915 Harley-Davidson, electrically equipped, excellent condition, with Swan sporting sidecar; £66.—Renier, 15, Cresswell Rd., Twickenham. [6703

1915 Harley-Davidson, electric model, and Gloria sidecar, perfect order; £55, or exchange.—Howes, 19, Limburg Rd., Clapham Junction, S.W. [6765

COLMORE Depot, Birmingham, Manchester, Liverpool, Leicester, for immediate delivery of all models of Harley-Davidsons, and spare parts. [0802

HARLEY-DAVIDSON 1916 Models delivered from stock on the best terms for cash, exchange, or easy payments; sidecars in stock to fit.—Below.

HARLEY-DAVIDSON, 1915, 7-9h.p., 3-speed, model 11J, electric lighting, horn, etc., with Harley model A sidecar, complete; £63.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C. [0492

LATE 1915 Harley-Davidson Combination, fully equipped, excellent condition, £80; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0861

1915½ Harley-Davidson Combination, 3 speeds, Canoelet sidecar, dynamo electric lighting, horn, new speedometer, tools, spares, condition A1; £70 cash.—Box L2,758, c/o *The Motor Cycle.* [6218

MOTOR CYCLES FOR SALE.

Harley-Davidson.

HARLEY-DAVIDSON 1916 Model 16F, and Canoelet car, wind screen, big F.R.S. lamp, Stewart horn, ridden 600 to 700 miles approximately, really good thing; £89/10; deferred payments, exchanges.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [6647

HARLEY-DAVIDSON, 7-9h.p., 16J model, with Gloria coachbuilt sidecar, hood and screen, complete with electric lighting outfit, spare tyre, tube, speedometer, and tools, done 900 miles, excellent condition; cost £110, accept £85.—Harley, c/o Staines Projectile Co., Ltd., Staines. [6728

Henderson.

RIDER TROWARD, 78, High St., Hampstead.—1915 Henderson, Bramble 18 gn. underslung sidecar, dynamo lighting, electric horn, new condition, mileage 2,000; cost £110, 65 gns. [6745

Hobart.

HOBART Motor Cycle, scarcely used; owner gone to the Front.—Particulars, Mann and Overtons, Ltd., 10, Lower Grosvenor Place, S.W. Tel.: Victoria 4634. T.A.: Sonpape, Sloane, London. [6699

Humber.

1912 3½h.p. 2-speed Humber, handle starter, very good; £18/10.—Stocks, Thurlstone, Sheffield. [X3858

1914 3½h.p. 3-speed Humber, lamp, etc.; £35; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0863

HUMBER Combination, 3½h.p., 2-speed, free, mag., B. and B., fast, in fine order and condition; £18.—Head, 31, Hamthorpe Rd., West Norwood. [0870

HUMBER, 1915, 3½h.p., 3-speed, nearly new; special price, £57/10.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter, and Tavistock Rd., Plymouth. [0842

1917 3½h.p. Humber, twin horizontal engine, semi-T.T. bars, handle-bar controlled clutch, quite new, just delivered, £75; with Mills-Fulford coach sidecar complete, £88; Douglas machines taken in part exchange.—Robinson's Garage, Green St., Cambridge. [6713

Indian.

INDIAN, 1915, 7-9h.p. road racer, lamps, horn, tools, spares, mileage about 5,000; £40.—Bristow, Lanercost, Wallington. [6738

7-9h.p. Indian, 1916, 2-speed clutch, Gloria torpedo sidecar, with lamps; £75; kick starter.—Williams, 10, King St., Twickenham. [6606

INDIAN, 7-9h.p., spring frame combination, beautifully equipped, new chains and tyres; called up; best offer.—G., 1, Kensington Park Rd., W. [6700

INDIAN, 1915, 5h.p., 3-speed, lamps, horn, etc., with Phœnix racing torpedo sidecar, fine condition; £58.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C. [0481

INDIANS, model C, in stock for immediate delivery, spring frame, 3 speeds, 2 electric lamps, and horn also speedometer; £78.—P. J Evans, John Bright St., Birmingham. [X3772

INDIAN, 7-9h.p. (1914), good as new, little used; owner at Front; will be sold by auction January 16th, 1917.—Charles Muskett, 88, Station Rd., New Southgate, N. [6621

INDIAN Powerplus, 7h.p., 3-speed, T.T., rigid frame model, Dunlop tyres, £75; spring frame touring model, with lamps and horn, £78.—In stock for immediate delivery at P. J. Evans, John Bright St., Birmingham. [X3766

INDIAN, 1914, 7-9h.p., 2-speed, electrically equipped, spring frame, all accessories, special Montgomery sidecar, Cape hood, screen, luggage carrier; £54.—Adlington, Fulham Military Hospital, Hammersmith. [X3802

INDIAN, 1915, 7-9h.p., 3-speed model C, electric equipment, large Millford de Luxe coachbuilt sidecar, with disc wheel, hood, screen, insurance policy, perfect condition; bargain, £63.—Lelliott, Chatsworth Rd., Worthing. [6768

INDIAN 1914-15 Genuine Coach Combination, 7-9h.p., spring frame, speedometer, lamps, tools, horn, large valuable skin motor rug, back seat; lot 45 gns.; trial.—Wires: Leeming, Westbourne, Vicarage Lane, Marton, Blackpool. [X3864

INDIANS, second-hand 1915 models: 7h.p. model C, with de luxe coach sidecar, £60; 5h.p., 3 speeds, with sporting coach sidecar, £52/10; 5h.p. solo mount, £50; all overhauled and guaranteed sound.—P. J. Evans, John Bright St., Birmingham. [X3762

7h.p. Indian, 1914, 2 speeds, electric light, speedometer, all accessories, with coachbuilt sidecar, whole machine as new; must sell, joining colours; £50, or near offer; seen any time by appointment.—Best, 80, Canbury Park Rd., Kingston. [6766

P. J. EVANS, Birmingham and Midland Indian Agent.—All models in stock for immediate delivery; 7h.p. T.T. Powerplus, £75; 7h.p. 3-speed spring frame, and electric light, £78; sidecars from 11 gns.—87-91, John Bright St., Birmingham. [X3763

INDIAN, 1915, 5h.p., 3 speeds, clutch, kick starter, and Mills-Fulford sidecar, all accessories, spare new Dunlop cover and tube, splendid condition, unused since January, 1916, ideal as solo or combination; £55.—Taylor, Maple Lea, Hindhead. [6634

Eliminating Weaknesses.

IN the early part of 1915 we ventured the suggestion that experts in motor cycle matters should be appointed by the Government to study the conditions under which motor cycles are used at the Front, and to make recommendations to manufacturers engaged entirely upon the production of war models. The object in view was, of course, the perfection of design by the elimination of weak points. It is common knowledge that certain details of design (we can fairly include all motor cycles in use at the Front) were entirely satisfactory when used under conditions obtaining in these Isles, but quite naturally perhaps were found to be lacking in strength or efficiency under the arduous conditions of war service. To particularise, we refer to frames, hub design, gears, the important question of mudguarding, spring forks and such like. Engines in isolated cases have not proved all they might be, and sidecars, too, have been found to be wanting in design. From accounts we receive from men at the Front who are competent to judge, certain troubles are still regularly experienced with specific makes of machines. These failures have been recurring for over eighteen months—in some cases over two years—are well-known to the men who handle the machines, and should be better known to the makers. When known and properly sifted, the manufacturers should be officially asked to heed the complaints. What is wanted, it seems to us, are experts who know the difficulties of the conditions to make periodic visits to the war zones and to confer with officers in charge of motor cyclist sections and repair bases—most of whom hold strong views—and then to return and advise manufacturers as to desirable changes or amendments in design. We believe this plan is adopted by the Royal Flying Corps in connection with aeroplane engines. A year ago we urged such a scheme of communication; later manufacturers' representatives visited the French front, but a solitary visit is not enough in the case of a motor vehicle. Besides, the weather and road conditions are so constantly changing.

It took many months of constant requisitioning before a suitably shaped handle-bar was standardised for our D.R.'s Overseas. The long touring bars often fitted led to many falls until riders themselves bent their bars to a suitable shape. We know an instance where hubs gave endless trouble for months and caused workshop mechanics much work, before the manufacturer even knew that this part required any attention. When *The Motor Cycle* drew his attention to the matter an improved design was produced.

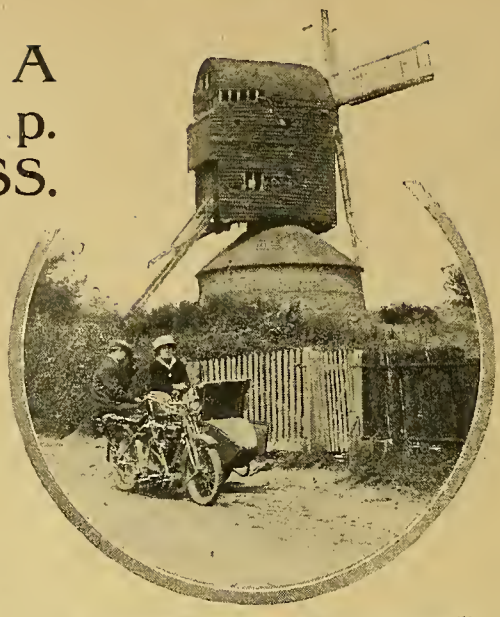
Another point in connection with military models is that different standards of finish are permitted; in one case machines are finished entirely in khaki, not a tiny plated part being permitted; in another instance the firm is allowed to deliver its standard products, all the parts being plated in the manner they would be for display in an agent's window: in still another instance the machines are all black. Now assuming that the question of colour finish is of minor importance—and we are not so convinced of that, seeing that motor cycles in war service have continually to be left exposed to the weather all night, and also must perforce be ready for use in all weathers, thus calling for the closest study in finishing processes to ward off rust and damp—some standard should surely be set by the authorities; either plating is of advantage or it is not of advantage. Personally, we should have imagined that in the summer months plated parts glinting in the sun would be of some guide to the enemy. We have heard it argued that rust is much less likely to attack parts of a machines which have been plated and subsequently neglected, and we are open to accept this view, but from the few remarks which we have made and which we could continue if it were necessary further to illustrate our point, it is clear that there is still some confusion in the production of the different patterns of war motor cycles.

An index to the advertisements in this issue will be found on the page facing the back cover.

A RUN ON A 1916 7-9 h.p. MATCHLESS.

A SHORT TRIP ON A POWERFUL AND COMFORTABLE MACHINE.

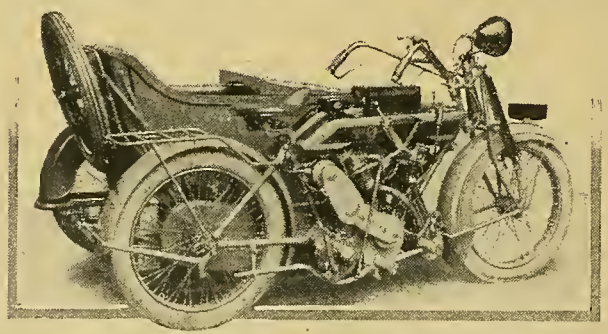
THIS machine was no manufacturer's specially tuned demonstration model, but a hard-worked hack belonging to a friend, which had had a season's wear. It was a fine autumn day, and as our course lay in the teeth of a south-westerly gale the engine was hard put to it for forty miles, but behaved splendidly. It would have done better had not the clutch been over-lubricated: this was caused by the relief pipe from the crank case throwing too much oil on to the chains and clutch—a fault which could have been easily remedied by closing the pipe a little. Despite this slight inconvenience the machine travelled extremely well and good time was made.



The Matchless halts beside an old windmill. These picturesque landmarks are rapidly falling into disuse, and the little country miller may in a few years cease to be.

Some Facts about the Engine.

The M.A.G. engine with which this outfit is equipped deserves the highest praise. It was not extraordinarily fast, but was a good puller, capable of a high average speed without making the slightest fuss, and totally devoid of all clatter and valve noises which are far too prevalent in many motor cycle engines. At 20 m.p.h. it was inaudible, and at higher speeds practically so, while the exhaust was quiet, though in no way throttled unduly. In short, the machine was one which a considerate driver would rejoice to use. Few people know how to remove the inlet valves of an M.A.G. engine. After the inlet dome has been removed the valve. if the motor has been run a long time since last taken down, will be found so firmly fixed as to be apparently immovable. If an attempt be made to lever the valve complete out of its seating the cage will probably be irremediably damaged. The process of removal is simplicity itself when once the procedure has been explained. Having taken away the exhaust spring the stem of the exhaust valve should be lifted until the head is found to be touching the inlet; next a nut or anything which will form a suitable distance-piece should be inserted between the bottom of the exhaust valve stem and the tappet, and the engine should be rotated, when the exhaust valve will push the inlet out.



A 1916 Matchless combination equipped with electric lighting set and interchangeable spare wheel. The engine is a 7 h.p. M.A.G

The particular engine referred to is fed with gas by an ordinary two - lever Amac carburetter, which is absolutely and entirely automatic. The air lever is permanently closed and is only moved to stop the engine. Occasionally, on very warm days, the engine can be persuaded to take a little air when travelling fast, but this is a very rare occurrence. This setting of the carburetter has been brought about by two factors—the fitting of the smallest jet the engine would take, and the extraordinary accuracy of the workmanship of the engine generally, which renders all joints perfectly gas and airtight. Of course, nowadays many two-lever carburetters are, to all intents and purposes, automatic in action, but the air lever is kept open instead of closed as in the instance mentioned above.

Mechanical Details.

To return to the machine in general; the change-speed was excellent and the clutch sweet in action, but the method of the control of the latter would have been better appreciated had the actuation been by a simple pedal similar to that working the brake and placed on the opposite footrest to that on which the brake control is situated. The other criticism is touching the handle-bars, which in the writer's opinion might be a trifle wider. Notwithstanding this fact the combination steered remarkably well, and even in unaccustomed hands proved a real pleasure to drive in traffic on account of the controllability of the engine and the excellence of the brakes.

The sidecar, the wheel of which is sprung, was luxuriously comfortable, and altogether the machine is one calculated to satisfy the most critical expert. Our return journey was made with the gale in our favour. Despite the fact that good time was made on the open stretches of road the throttle was only opened on hills. In the meantime, however, the new Matchless flat twin claims first attention, and when the factory of Messrs. Collier and Sons at Plumstead resumes its normal state the Matchless sidecar promises to become increasingly popular.

OCCASIONAL COMMENTS

BY 'IXION'

Acceleration.

I HAVE never—short of a big racing car—tasted such fiendish acceleration as a well-tuned four-cylinder motor cycle affords; it must be sampled to be believed. The response to the throttle is simply terrific, and the machine positively leaps away. By comparison the flat twin is certainly sluggish, unless it is geared rather low, or unless full advantage is taken of the gear box in snatching a jump. I do not think the flat twin is inferior to the vertical single in this respect, though some people say it is. At any rate, there are two features of value in acceleration—the first is its rate, the second is its smoothness. The four-cylinder has both. It gathers speed at immense velocity in a given distance, and it does so without rousing any sensation of effort. The flat twin accelerates less rapidly (at any rate, on equivalent gear ratios), but with almost equal smoothness. The vertical single accelerates less rapidly than a four-cylinder, and at about the same rate as the flat twin; but it labours very perceptibly under the process by comparison with the four and the twin alike; there is a sensation of hammering. In such comparisons it must be remembered that the 500 c.c. flat twin is a suckling compared to the four-cylinder or the vertical single; comparatively few designers have tackled this type of engine, and those who have can only claim a short acquaintance with its possibilities. I incline to believe that the flexibility, acceleration, and gear-accepting qualities of the larger flat twins will improve rapidly during the first few years after the war.

The Perfect Two-stroke Plug.

I AM still looking for a satisfactory sparking plug for the more exacting baby two-stroke engines. There are some engines which are not fastidious, though I am not good enough technician to know whether the cooler engines tolerate ordinary plugs chiefly by reason of low compression ratios or a port design which ensures good scavenging. For example, my baby Levis engine (to name one make) will work on almost any sort of plug; but I have owned others which rapidly overheat all ordinary plugs. The special Sphinx two-stroke plug is easily the best I have tried, but it will "incandesce" on a two-speeded baby up a long hill. The addition of the Fletcher cooling radiators enables it to resist the hottest baby engine I know; but you cannot use the Fletcher lower radiator (*i.e.*, that which replaces the ordinary s.p. washer and cools the butt of the plug and the outer electrode) unless a tube spanner is applicable, as the dished copper radiators prevent any other spanner from getting a grip. So I am still without a plug suitable for the hotter type, and equipped with a plug mounted vertically and centrally on the cylinder head; because there is no clearance to use a tube spanner and mount the auxiliary coolers on the Sphinx plug. I met a man using a Lodge racing plug on such an engine, which is foolish. All baby two-strokes are naturally somewhat oily engines, and the Lodge racer, being designed to keep its points very cool, cannot burn oil off itself. The crux of designing a two-stroke plug lies in the fact that the electrodes must keep cool, and yet must not accumulate carbon.

Carrier Bags.

NOT long ago I appealed to the trade for a carrier case constructed on matchbox lines, and with its contents accessible by opening a single lock at the end. Messrs. J. B. Brooks and Co., whose experience is, of course, unrivalled, tell me that they used to make such a case, but that it did not sell. They further find that motor cyclists will not buy bags which depend purely upon a lock, but insist on having straps as well. Evidently I am not the only rider who (*a*) has left his key-ring at home, and gouged an expensive leather case open with a cold chisel, and (*b*) paid good money for a locked carrier case, and had the lock choke up with dust after a few touring trips. I was rather interested in the catalogue which accompanied the firm's letter. They make first-class little cases for any and every accessory; and they further list ingenious full and half leggings, attached over the trousers by spring clips, which are just the thing for doubtful weather, when one does not need waders or oilies.

"Some" Pluck.

A PARAGRAPH on an unusual subject for this paper. Who is the bravest living Englishman? No, no, no; spare me these war yarns. They show courage of a type, I admit; courage in comradeship, where thousands face a speedy death side by side; courage when the blood is up, and danger has shrunk to a commonplace. The courage I shall now retail is of a higher, sterner sort—courage in solitude, the manful facing of a lonely death in cold, deliberate blood. It is my often unhappy lot to test various contraptions forwarded to the office by inventors, some of them sane, others—! Last week I opened a bulky parcel addressed to "Ixion," and carefully unfolded a most imposing looking waterproof, built of most admirable cloth. It was obviously large, and as it unfolded, it seemed a trifle shapeless. The staff were called in to collaborate. At last the design was solved. It had a round hole, with rain-turning collar, through which one thrust one's head, poncho-wise; it covered not only one's person, but one's machine, and was attached thereto by numerous little straps and tapes and ribbons. It happened to be raining at the time, and the staff gleefully hauled me into the yard, perched me on my saddle, stuck my head through the hole, and strapped the abomination firmly down. I was as helpless as a trussed fowl. I could not think of anybody who would release me but my faithful wife, resident many miles away; so I manfully operated my kick-starter and rode home.

A DOUGLAS IN THE DESERT

Despatch Carrying in the Desert of Sinai

LITTLE did the section think when they were carrying out their training in England that their destination on active service would be the deserts of Sinai. Like most D.R.'s in training, we had pictured to ourselves the mud fields of Flanders as the scene of our operations. Our training, too, at Biggleswade and Houghton Regis certainly seemed to justify the belief that we were bound for France, for there we plunged recklessly through water splashes, pushed and coaxed our bicycles through ploughed fields, invented patent mud-scrapers to prevent our mudguards clogging, and experimented with various devices for the protection of the front plug during deluges of rain. All apparently wasted, however. A signal company was required to accompany a certain division to the Sinai Peninsula, and we were the lucky D.R.'s chosen to support that signal company.

Our Destination.

Our arrival at the scene of operations was extremely depressing. The previous night we had entrained at a place some 150 miles away. The entraining process started at 7 p.m. and finished at 2 a.m. the next day. It is by no means child's play to get a signal company on to an Eastern train. First of all the mules have to be reckoned with. They seem to have a firmly-rooted objection to being led anywhere, and in particular they detest being packed ten deep in a cattle truck. So they kicked and reared and plunged, scattering confusion and disaster wherever they went. Having had previous experience of mules, we very wisely removed our "Dugs" to a far-distant corner of the yard and mounted guard over them. Eventually every mule was aboard, and kicking with might and main at the sides of the truck. Then cable carts, ration carts, tents, and baggage had to be manœuvred into the train, and, finally, the men squeezed into the remaining corners. We had two large trucks reserved for us and our bicycles, and with their usual pride of race the D.R.'s rode up in perfect order and were on board in fifteen minutes. Then followed a sleepless night's ride, which was relieved by some of the boys trying to ride their bicycles round the narrow compass of the truck. I believe some of them could and would ride along a telegraph wire if no other road were available.

Eventually we stopped—a longer stop than any of the preceding ones—at a place apparently in mid-desert. Astonishment could be read on every face. Was this the place we were destined for, this inhospitable waste of sand and scrub? Did they expect us to ride motor cycles over ground previously traversed only by camels. Many were the groans and curses uttered until someone suggested an alternative to motor cycles—mules. The one word was enough. Unanimously we decided that if it were humanly possible we would ride motor cycles over that desert.

The next morning we started work. Our signal office was a combination of dug-out and sand bag shelter, and we lined our Douglases up some 200 yards away in a neighbouring hollow, and screened them as far as possible from the prying eyes of aviators. Previous to going on duty we had scouted round and found a fairly hard camel track that seemed to link up, more or less, the various units of the division, but to reach this "road" we had to cross a belt of particularly loose sand, which was punctured here and there by pot-holes filled to the level of the surrounding ground with drifted sand. We had not long to wait for the first despatch. We gathered round to see what sort of a show No. 1 on the roster would put up. With a roar of the open exhaust the little Douglas went off, but soon the back wheel was describing snake-like movements in the treacherous sand. But the rider was our best man and not easily unsaddled. Now swinging from side to side in the loose sand, now thrown a foot or so in the air as his front wheel struck a hidden piece of rock, he made his way out to the track, and was soon bounding from bump to bump in top gear. That morning nearly everyone of us bit the sand in turn. It was a common sight to look out across the desert and see one of our D.R.'s lying in the sand and grabbing at the exhaust lever to stop the roar of the engine, which was probably racing on full throttle. But experience brings proficiency, and within a week we were all expert sand riders.

Riding Over Sleepers.

So far all was going well with us. We were evidently certain of being able to deliver all messages within the divisional area. The crucial test came when we had to take "urgents" to the Army Corps. Now there is no pretence at a road between the Division and the Army Corps at present. The only means of communication is the single railway line. Could we use this as our "road"? was the question everyone asked. At

A Douglas in the Desert.—

first glance it seemed well nigh impossible. The rail led straight through the desert, and there was no path or track on either side. Further, the sleepers protruded from two to six inches from the bed of flints on which the rails were laid. Nevertheless we were determined to attempt it. The first man who attempted it got through by a superhuman effort, and returned with every muscle in his body quivering from the awful pounding he had received. He described the journey as a choice between bumping from sleeper to sleeper on the track and sticking fast in the loose drift sand by the side of the track. No wonder that after riding there and back, a distance of twenty-eight miles, he was completely exhausted. Still, determined not to be beaten, we surveyed the track and mapped it out. You could ride for a certain distance between the rails, then take to desert and strike well out, when you would find a fairly hard stretch of sand; return again to the rails farther up for about three miles, and then strike out again on the opposite side of the track. When within about four miles from the corps headquarters one came across a camel track and followed that till it developed into a hard road leading straight into the camp. The initial attempts were naturally hard on the machine as well as on the rider. The frames of two machines were broken close to the head, footrests were swept away by rocks and railway lines, tanks sprung mysterious leaks, and tyre burst wholesale, but, on the whole, the bicycles stood up to their most arduous test splendidly. Probably all the journeys could have been done quicker and with more comfort to ourselves with a higher powered bicycle fitted with kick starter and clutch, but as these were then unobtainable we had to make the best of our little Douglases.

Frequent Overhauls.

There is one very curious effect that active service has on a D.R. In England he cordially dislikes cleaning his bicycle, and only does very necessary repairs and overhauls. But on active service, when he knows that his own life and often that of hundreds of others depends on his efficiency, you will find him constantly overhauling, repairing, and cleaning. It is no exaggeration to say that the D.R.'s motor cycle receives equally as much care and attention on active service as do the horses and mules; and anyone who has been on active service will know that this is saying a great deal.

With regard to the life, I can only say that no one in our section regrets being sent here now. The food is extremely good, and we D.R.'s do ourselves very well after one of our number has been up to the Army Corps. He always returns with his pannier loaded with vegetables, tinned fruit, chocolate, and cigarettes. Generally these arrive in good condition, for experience has taught us how to pack the things up well.

In conclusion, I must not forget to pay a tribute to *The Motor Cycle*. Of all papers it is the most eagerly sought after, and I can honestly say it is read from cover to cover. We are especially interested in the Military Section and in the various articles which from time to time appear on recent developments in motor cycling. No one is more eager than the D.R.'s to return to dear old Blighty, but not

"Till the hurly-burly's done,
Till the battle's lost and won."

H. W. GILBERT (Cpl.)

The Use of a Shifting Spanner.

GOOD kit is very often spoilt by thoughtless or careless handling, and the brand of the beginner is generally to be found on the keys and spanners contained in his tool roll. The actual destruction of kit is not in itself a very serious matter, as tools easily can be replaced, but it may be taken as certain that if the tools indicate bad usage, the nuts, etc., throughout the machine will be found in the same worn and mishandled condition. A good shifting spanner, if properly used, should last for years, but a few weeks in the hands of a tyro will reduce it to a nerve-shattered and weak-jointed wreck.

One of the most frequent misuses of large size shifting spanners is in the application of the hammer. A shifting spanner should never be hammered except in cases of dire necessity, and then great care should be taken that the jaws are tightly gripping the nut, otherwise the stem of the spanner will become "sprung," so that it will refuse to work easily, while in all probability the nut will be ruined.

If a hammer *must* be used, the blows should be delivered to the handle of the spanner on the side opposite to the jaws—that is, with the bottom jaw of the spanner pointing in the direction the nut is intended to turn. If the spanner is placed wrong way on and hammered, a few blows will probably suffice to ruin it, and at no time should pressure be applied to a shifting spanner in the wrong direction.

Shifting spanners are not intended for the purpose of removing or tightening valve caps, which must always be hammered. A special key is provided with every machine for this purpose, and not only does the use of a spanner spoil the cap, which is made of soft metal, but the spanner itself suffers.

MOTOR CYCLES IN JAPAN.

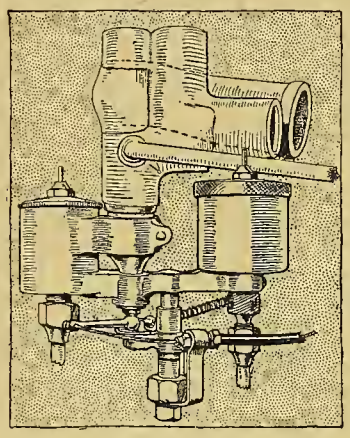
Riders of a B.S.A. and Premier crossing the Kurihashi ferry on the river Tamagawa. The photograph was sent to us by E. V Stevens, of Sagasni, Japan.

A PETROL-PARAFFIN CARBURETTER.

Device for utilising both fuels separately or mixed.

WE have recently received particulars of a conversion, which Mr. Willis of Wolverhampton has made to his Triumph carburetter, the idea of which forms the subject of a provisional patent.

In order to obtain the best running from petrol-paraffin mixtures, Mr. Willis devised the idea of fitting another float chamber to his Triumph carburetter, so



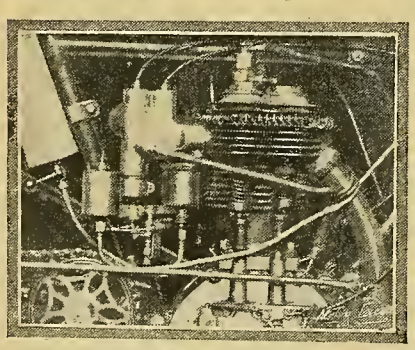
An ingenious manner of utilising paraffin as a fuel.

that either fuel might be used without the difficulty of having to drain the contents of the float chamber in order to start or run on pure petrol.

The second float chamber is so attached that a tap situated between the two float chambers controls the distribution of the fuels, either of which can be admitted to the jet at will, or, if so desired, only a portion of each fuel can be admitted.

When starting from cold the tap is turned so that only the chamber containing pure petrol from the small auxiliary tank is connected to the jet, but when the engine has warmed up, the petrol is gradually turned off, and little by little, the heavy fuel is turned on to the jet. If more power is required than can be obtained from the heavy fuel, then the tap is adjusted so that a proportion of pure petrol also enters the jet and mixes with the heavy fuel, so forming a more volatile mixture.

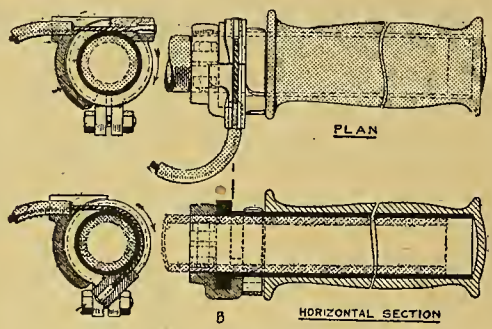
The heavy fuel feed pipe is arranged to pass round the exhaust pipe before entering the float chamber, while in order still further to facilitate the vaporisation of the heavy fuel, a pipe is taken from the exhaust and passes through the spray chamber of the carburetter just above the jet.



A petrol-paraffin carburetter fitted to F. H. Willis's Triumph. A separate float chamber is used for the two fuels.

A TWISTING HANDLE CONTROL.

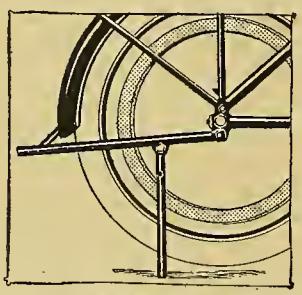
A TWISTING handle grip of extreme simplicity has been patented by Mr. S. Sadler, of 26, Claremont Rd., Sparkbrook, Birmingham. The revolving handle carries a boss to which is anchored a Bowden cable, a stop for the



outer casing being fixed to the handle-bar. The wire then leaves the handle-bar at right angles, but can be carried in any direction required. The rotating part is provided with a flange which, running in a groove, prevents the grip from sliding off the handle-bar.

A "JACK" STAND FOR MOTOR CYCLES

A NEAT and compact form of "jack" stand for a motor cycle is shown in the illustration herewith. It will be seen that the main part of the stand is of the conventional type, with secondary members that drop down when the machine is to be raised on its stand.

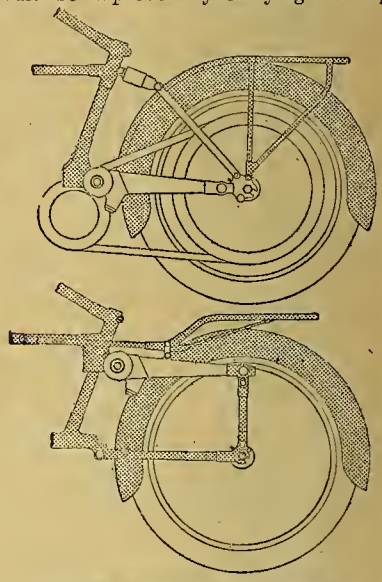


A "jack" stand for motor cycles, which enables the machine to be raised on the stand with the minimum of effort.

Foot pressure is then applied on the stand proper, which acts as a lever and lifts the rear wheel from the ground. A slight backward pull on the machine then swings the stand in the ordinary position. This is accomplished while the rider is standing alongside his machine holding it erect.

ENCLOSED SELF-LUBRICATING LEAF SPRINGS.

FOLLOWING upon our description in *The Motor Cycle* of December 14th of a motor cycle spring frame having the rear springs enclosed, a motor cyclist, Mr. Ernest Moor, of Gravesend, who has been a reader of this journal since his school days, sends us a design for enclosed and self-lubricating leaf springs. This design has much to recommend it, and is very neat in outward appearance. Two forms of springing are illustrated, but we suggest that the lower design would be improved by carrying the sup-



Showing various designs of encased rear springs.

ports from the spring to the axle in a loop over the wheel, and so increase the lateral rigidity. The lubrication is carried out by means of a plunger pump operated automatically by the rise and fall of the machine when running. In the upper design the leaf springs are supplemented by an enclosed coil spring below the saddle. The carrier is unsprung in the upper design, and partially sprung in the lower.

A ROTARY VAPORISER.

WE illustrate herewith a rotary vaporiser, the invention of one of our readers—Mr. A. E. Sampson, of Penketh. The device is automatically actuated by the movement of the incoming gases. This sets the rotor working

A vaporiser intended for existing machines patented by A. E. Sampson.

at high speed, and very thoroughly combines the air and petrol passing through the induction pipe. No heating of the pipe is said to be necessary, even when heavy fuels are used.

THE CASE FOR THE LONG STROKE

By JAMES L. NORTON A.M.I.A.E.

EXHAUSTIVE consideration of the subject of long *v.* short stroke engines cannot well be entered into in this journal, the subject being a complex and intricate one with many side issues, which I shall, as far as possible, avoid where the root of the argument is not affected. Before dealing with the several arguments of "A.A.S." under "Bearing Pressures," issue of October 19th, permit me to call attention to features in the article which give one the impression it was a biased and unfair attack upon the long stroke engine, rather than a true endeavour to determine the respective merits of either type. In the first place, "A.A.S." compares the reciprocating weights of two engines of dissimilar size, the long stroke capacity being roughly 8½% greater than the medium stroke; the fact that piston weight increases more rapidly than in direct proportion to an increase in size, and its effect upon inertia stresses are ignored, and this renders his figures in this connection of little true value.

The subject of bore-stroke ratio is a controversial one. Ever since the earliest days of motoring the subject of long *v.* short strokes has occupied the close attention of engine designers. An article on "Bearing Pressures," which appeared in "The Motor Cycle" for October 19th last, was, perhaps naturally, interpreted as being unjust to the long stroke engine by Mr. James L. Norton, A.M.I.A.E., than whom no greater exponent of the long stroke engine exists. His contribution to the subject is appended.—ED.

Comparative pressures may only be fairly considered in conjunction with equal power development.

Further, where "A.A.S." imagines he has an effective counter—referring to crank pins—he admits "the pressure is momentarily greater for a medium stroke engine," but later, in order to score a point, he says, "allowing *equal* gudgeon pin pressures," so altering his conditions in order to arrive at desired conclusions. (In your issue of December 7th his arguments are again similarly misleading, the figures showing a greater total piston pressure for the short stroke, where he can apparently afford to admit the fact, but, later—*re* gudgeon pin—he says, "As we may assume the pressures are equal in either case, etc.") Charity compels one to try and believe such misleading statements are inadvertent.

Yet once more must I draw attention to an assumption at once misleading and unfair, and then turn to the more congenial matter of dealing with the arguments proper, or, I greatly fear, my readers will accuse me of becoming vituperative, which I wish most earnestly to avoid becoming.

Both the reciprocating and revolving masses of the medium stroke engine which require balancing are greater than those of the other type, and yet "A.A.S." assumes both to be the same amount, *i.e.*, 4 ozs., out of balance, instead of basing his figures upon the fair assumption that the unbalanced mass is the same percentage of the total mass in either case, there being nothing to prevent both engines being balanced to the same degree of accuracy.

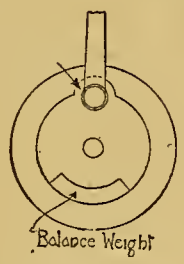
Failing this, his conclusions are of no effect.

Bearing Sizes.

"A.A.S." states: "The bearings can be larger for a medium stroke big bore engine than for a long stroke small bore engine, other conditions as specified being equal."

In this connection special attention is given to the crank pin with a drawing intended to prove that, owing to the proximity of the flywheel rim, a large bearing cannot be used. This, as pointed out by other writers, is a fallacy. If desired, a recess may be put in the rim as fig. 1 to permit of an exaggerated crank pin, not only without detriment, but with slight advantage to balancing. This, in fact, is the usual procedure.

There is, therefore, nothing to prevent the crank pin bearing of the long stroke being as large as desirable, but, whatever size be used, a still larger bearing is compulsory in the shorter stroke to obtain the same resistance to wear, as will be seen later. Incidentally, the usual type of crank pin bearing and the main shaft of a truly *short* stroke motor cycle engine are in such close proximity that comparatively small dimensions *are compulsory*. It is obvious that the big bore will admit a longer small end bearing than the long stroke engine, but this advantage is quite eclipsed by the greater pressure per square inch it has to support. Given that one-half the total length of either gudgeon pin is supported by the piston bosses, and that the total length is roughly equal to the bore (neglecting clearance), we have in the short stroke a bearing 1¾in. long against 1⅝in. in the long stroke, both of ⅝in. diameter.



The usual provision for crank pin in flywheel rim of a long stroke engine, which makes a smaller bobweight possible.

Now let us see what approximate explosion pressure per square inch of projected area each bearing is subjected to, allowing a maximum load of 250 lb. per square inch of piston head in both cases, this pressure being fairly well within the mark.

Long stroke, bore 82 mm. $\pi r^2 \times 250 =$ 2,046.4 lb. on piston head = 2,014.9 lb. per square inch of projected area of gudgeon pin bearing.

Short stroke, bore 88 mm. $\pi r^2 \times 250 =$ 2,356.9 lb. on piston head = 2,154.8 lb. per square inch of projected area of gudgeon pin bearing.

The Case for the Long Stroke.—

For brevity's sake I have omitted showing the entire calculation. It will be seen that the short stroke bearing has an additional load of approximately 140 lb. per square inch; it is therefore in effect much smaller, and will require rebushing more frequently than the long stroke engine, with its smaller total load and pressure per unit of bearing area.

"A.A.S." states: "Although the pressure is momentarily greater for a medium stroke engine, its greater bearing area helps to equalise matters."

It is shown that the assumed greater crank pin possibility of the big bore engine does not exist, and as the greater pressure on its bearing is admitted—this must be approximately 20% greater in order to yield the same power per revolution—the disadvantage in this connection is all with the shorter stroke.

"But the long stroke suffers wear for a greater distance of its bearing travel," "A.A.S." continues. If the *smaller* pressures of the long stroke are distributed over a greater distance, then surely the long stroke has a double advantage.

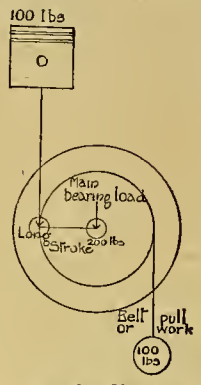


Fig. 2.—Showing load on long stroke main bearing for 100 lb. pull.

"A.A.S." further states: "On the main shaft bearings the wear will be equal so far as explosion pressures are concerned, as the total power transmitted will be equal." This assertion is entirely wrong. We will, for the moment, assume an impossibility, *i.e.*, that the total power transmitted by one stroke of the long stroke engine can be equalled by one of the shorter stroke, both having the same gear. With a force or pressure of, say, for example's sake, 100 lb. on the crank pin of the long stroke engine, and assuming, for simplicity's sake, there is no loss in transmission, so that the amount of work equals the power or pressure, and the effective pulley diameter is equal to the stroke length (ignoring the angle of belt pull which will not affect the issue), we have the following. See fig. 2. Here we see that the load sustained by the long stroke bearing is the total of pressure 100 lb. + 100 lb. load = 200 lb.

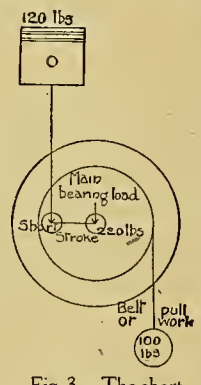

Fig. 3.—The short stroke requires a greater piston pressure to do the same work as a long stroke, with consequently greater bearing pressure.

Now turn to fig. 3, in which the shorter stroke engine, with its 20% shorter crank or lever, is shown doing the same work, it will be seen a 20% increase of pressure or power is necessary in order to balance the levers (see "A.A.S.," *The Motor Cycle*, November 16th.) Pressure 120 lb. + 100 lb. = 220 lb. load on main bearing, or 10% greater than that on the long stroke bearing. *If this were not so the short stroke engine would do only 80% of the work of the long stroke.*

It is stated the "peculiarity of the long stroke engine of hanging on under load, at low speeds especially, is not a help to long life for the bearings by any means."

This perhaps inadvertent admission that the long stroke engine has the peculiarity, *i.e.*, advantage, of *maintaining* a greater power output, and the statement that such does not help the bearings, almost tempt one to reply in sarcastic vein, apparently the short stroke owes its alleged longer bearing life to its comparative inefficiency and lack of power.

Cylinder Lubrication Difficulty.

On this question it need only be said that for the long stroke such difficulty does not exist, that a greater proportion of the area of cylinder wall is permanently shielded from the oil spray by the piston of the short stroke engine, and that not only does the smaller piston of the long stroke leave a greater length of cylinder exposed to the oil, but the lower portion of the piston itself may be, and usually is, subjected to a direct oil spray from the flywheels, this, too, on the side taking the load. This oil is carried up the cylinder walls to a point higher than the lowest position of the piston rings, which descend into a flood of fresh oil, and are thus directly and copiously lubricated every stroke. This very distinct and valuable advantage is denied the *short* stroke engine. as instance results at Brooklands.

Lubrication of Big End.

This bearing, when depending upon splash, is, perhaps, more precariously situated than any other one in the engine. The short stroke bearing, revolving as it does in that portion of the crank case most void of oil, is again at a disadvantage, whereas the path of the long stroke big end is where the oil spray is almost at its maximum density, and where the friction of the crank case walls, tending to retard its speed, possibly causes a slight pressure of oil—due to inertia—upon the bearing.

Cylinder Wear and Piston Ring Pressures.

Here we have possibly the greatest frictional loss in an engine. "A.A.S." omitted referring to this important feature in his article, and dismisses it with slight consideration in his letter of December 7th, but one has only to examine a cylinder after use to realise that the effects of piston pressure may almost be ignored when compared with the serious loss due to ring friction. The ridge in a cylinder, indicating the sudden increase of bore diameter due to wear, is not at the end of the path swept by the *piston*, but that swept by the piston *rings*. Unfortunately, piston ring pressure causes a dead loss; there is no return for it, as there is for piston pressure due to the increased angularity of the long stroke connecting rod, for, *whatever this pressure may be*, it is transmitted directly into turning effort on the crank pin. The wearing effects of this pressure need scarcely be considered, except upon two of the four strokes of the cycle, and very little upon one of these, *i.e.*, the compression stroke, whereas the piston ring loss is at a maximum over each of the four strokes.

Static friction, or the friction of rest—far more serious per unit of pressure than that of motion—comes into effect at the end of each of the four strokes.

(Fit a piston with its rings into a cylinder and endeavour to reciprocate it; the serious effort to start

Ariel

The Motor Cycle of Supreme Reliability

—by performance in severely contested reliability trials, in private service all over the world, and on war service.

It is impossible to give the history of Ariel reliability performances in an advertisement. Our new 32-page Art Catalogue contains all particulars. Ask us to send you a copy.

TRADE MARK WOOD-MILNE

The Case for the Long Stroke.—

it moving, compared with the effort of sliding it *after* starting, will be noted.) But, it will be said, both engines suffer from the same disadvantage. Quite so, but not nearly to the same extent; the difference being a serious debit to the short stroke, particularly if it be remembered that the short stroke rings are not so effectively lubricated as those of the long stroke.

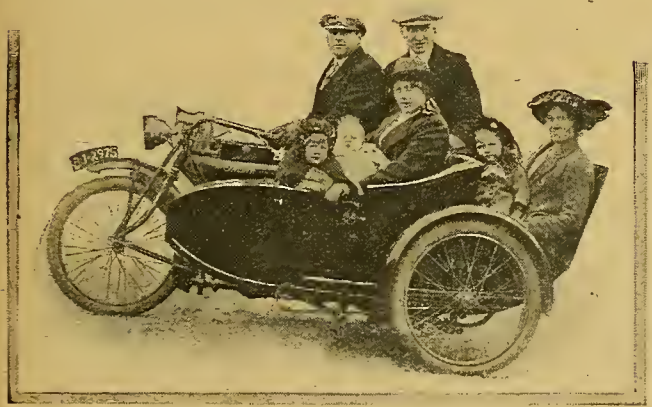
The pressure of rings may be found by formula, the pressure per inch being determined by the thickness and diameter of ring and the width of gap. It is natural to assume that the larger ring will be proportionately broader, thicker, and with a wider gap, but, in order to avoid unnecessary figures, we will suppose the short stroke ring to have the same pressure per square inch as its smaller rival, and will put this at the somewhat low figure of 5 lb. ("A.A.S." suggests 10 lb. to 15 lb.)

Long stroke ring 82 mm. $\times \frac{5}{32}$in. = area 1.58525 square inch $\times$ 5 lb. = 7.92625 lb. total pressure on cylinder walls.

Short stroke ring 88 mm. $\times \frac{3}{16}$in. = area 2.04182 square inch $\times$ 5 lb. = 10.20910 total pressure on cylinder walls.

Here in the most active power-consuming feature of the engine, which gets in its fell work every stroke regardless of throttle position or work required, be it little or much, running light or under load, the short stroke suffers an irredeemably increased loss of approximately 30%.

That portion of the article under the sub-heading "Centrifugal Pressures" appears to be a confusion of issues and misstatements, based upon erroneous assumptions and unfair comparisons (see introductory notes), and I shall not, therefore, attempt to deal with it in detail. As, however, it all centres around inertia stresses, I will as briefly as possible state the position of the two engines in this respect, commencing with a statement of the fact—which, I think, is never denied—that at higher than average revolutions, and under such conditions only, the long stroke connecting rod bearings may be subjected to higher mean inertia stresses than the short stroke at the same high revolutions, but—and here is the crux of the matter—*it is never necessary to run the long stroke at so high a speed as the short stroke to develop equal power*, or, in the case of a motor cycle, the same road speed. This fact, I think, is generally acknowledged, but it is not generally realised exactly what this means.



CAN THE LIGHT CAR EQUAL THIS?

One advantage seldom mentioned in discussions on sidecar *versus* light car. A 7-9 h.p. Indian Powerplus with double-seated sidecar owned by Mr. B. J. Haste, of Bramford, Ipswich.

SOME NUMBER PLATE.

A Belgian rider in one of the densely wooded avenues approaching the city of Antwerp. Prior to the war, motor cyclists in Belgium were obliged to carry number plates of ungainly size on their machines.

Every mechanical loss, *i.e.*, friction caused by explosion pressures and piston rings, unbalanced forces and inertia pumping efforts, valve operation, etc., is, with its attendant wear, multiplied in the short stroke engine owing to this necessity for higher revolutions. And here the importance of the V^2 factor and its effects with increase of speed upon the heavier reciprocating parts of the short stroke must not be overlooked. There are advantages in the use of a short stroke, but these in no way apply to the bearings, and consist in the possibilities of a lesser total weight, and, to the manufacturer, the fact that an extremely high standard of accuracy is not quite so essential as with long stroke engines.

I think we may safely deduce the following from our considerations:

The short stroke engine bearings are subjected to greater explosion pressure per unit of area, and, therefore, greater wear than the long stroke at equal revolutions.

At equal power output these pressures are still further increased in the short stroke engine, which may, in consequence, be expected to have, comparatively, a shorter life.

The short stroke engine bearings are subjected to greater inertia stresses than the long stroke at moderate speeds, but these stresses increase more rapidly in the long stroke with an increase of speed, and there is, therefore, a point at which they become greater than in the short stroke. There is some doubt if this critical point is often, if ever, reached, excepting in track machines, particularly when one remembers the increased revolution speed of the short stroke necessary to equal the greater power of the long stroke.

In conclusion, may I quote Mr. F. W. Lanchester in one of his papers before the I.A.E.? It will be remembered the Lanchester car was one of the last to abandon the use of the short stroke. "*Under all circumstances the short stroke is at some slight disadvantage on the score of mechanical efficiency.*"

TIMES TO LIGHT LAMPS.

GREENWICH TIME.

A Government Appointment.

Mr. Percy Martin, the managing director of the B.S.A. and Daimler Co.'s, has received an important Government appointment, and will, we understand, represent the Ministry of Munitions on the Air Board.

Petrol for our Fighting Men.

Officers home on short leave will be glad to hear that they can obtain from the Petrol Control Committee, 19, Berkeley Street, London, W., licences for one or two months' supply of petrol, subject, of course, to the usual restrictions, *i.e.*, a motor cyclist can obtain either two or four gallons per month.

The Man Power Board.

We are pleased to learn that Mr. Eric N. Gamage, a director of Messrs. A. W. Gamage, Ltd., and eldest son of Mr. A. W. Gamage, has been appointed by Mr. Neville Chamberlain to take charge of the Suggestions Department of the above Board.

Another Name for the Tanks.

Is it true that among the Scots regiments the "Tanks" are known as "Uncanny Lorries"? *London Opinion* says that a reader from beyond the border has suggested the nickname at any rate.

Flat Twins of Moderate Capacity.

We have received from Mr. Granville E. Bradshaw some lengthy and conclusive comments upon the subject of flat twins, and the contention of a writer in a contemporary that "While the 350 c.c. opposed engine is singularly successful, engines of a larger capacity had yet to prove their success. *The development, and consequently the efficiency, were limited because obvious faults were inseparable from the design. . .*" As, however, we have already devoted a considerable amount of space to this topic we do not propose to continue the discussion at present, particularly as there can be no two opinions amongst engineers as to whether it is possible to make a really efficient flat twin of over 350 c.c. capacity, and *that*, neglecting side issues, is really the disputed point. This has been conclusively proved by "Ixion," Mr. Bradshaw, and other contributors to our pages.

A Petrol Query Settled.

The Petrol Control Committee tells us definitely that one may go on using personal petrol licences until all the petrol sanctioned by it has been purchased—this quite apart from whether or not one has taken all the spirit before the end of April (for a car licence) or March (for a motor cycle licence).

Prisoners to Mend Roads.

The Essex County Council has asked the War Office to arrange for the employment of German prisoners of war in repairing Essex main roads. All of the members of the surveyor's staff who are of military age have been released for road making behind the British lines in France, and ten steam rollers have been lent for the same purpose. For over two years such a course has been urged in various quarters.

Enriching the English Language.

The use of the term "flat twin" in preference to horizontally-opposed engine is merely a case of economy in words. Americans cannot agree whether to accept the term. Some time ago, Mr. E. B. Holton, a leading motor cyclist over the water, seized upon the term with enthusiasm, and said: "As it is good, I hope we adopt it into our own lingo. It is the English appellation for a doubly opposed motor. The beauty of it is that it fully describes the type, and at the same time is short."

A departmental manager of the Hendee Co. at first thought it was not bad, but that it would hardly do in the States, as it would quickly become confused with an American slang phrase. Be that as it may, journals throughout the world (including American journals) are following the lead of *The Motor Cycle*, and even if our American friends do not put their hall mark upon it, they will find that ere long it will become the accepted term among motor cyclists.

SPECIAL FEATURES:

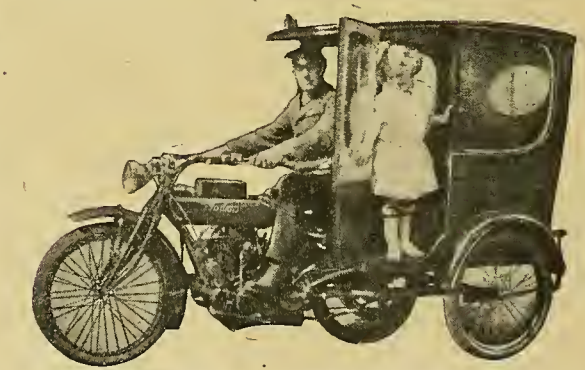
THE CASE FOR THE LONG STROKE.
A DOUGLAS IN THE DESERT.
A RUN ON A 1916 7.9 h.p. MATCHLESS.

Six Miles an Hour Speed Limit.

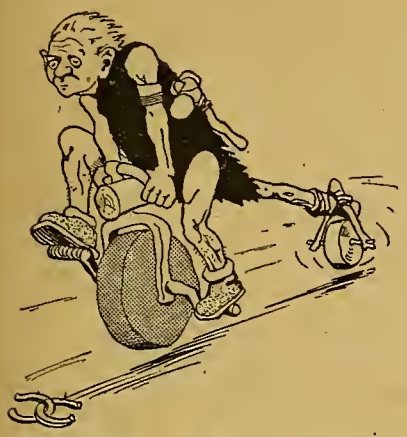
The Town Council of High Wycombe has carried a resolution stating that the speed limit of motor traffic should be reduced to six miles an hour after dark, and that an application be made to the Local Government Board for an Order fixing the speed limit as suggested. Alderman Ellis said that Wycombe traffic was a thousand times more dangerous than London, Councillor Elsom concurring. If that is the case, and we would not for a moment doubt the truth of the alarming statement, then six miles an hour certainly should be the maximum.

Motor Trades Debating Society.

A subject of extreme importance to those interested in the great labour problem will be discussed by the above society at the R.A.C. on the 17th inst., the resolution being "that restricted output is justified." Mr C. Latham will support the resolution, opposed by the vice-president, Mr. Powell. Arrangement can be made to attend the debate by communication with the hon. secretary, Mr. C. D. Clayton, 52, Shaftesbury Avenue, Piccadilly, W.



The limousine sidecar has made its appearance in America. It rejoices in the name of "rear car." The occupant is Miss Alice Neumann, a child actress. The vehicle is luxuriously upholstered in silk tapestry, and fitted with electric light.



HUMOUR FROM THE WAR ZONE.

A clever drawing of a pre-historic "despatch" rider (coloured in the original) was sent to us with seasonable greetings by the despatch riders of the XIII. Corps in France.

The National War Funds.

At the week-end the principal war funds stood as follow :

The Prince of Wales's Fund (distributed £3,529,719)	£6,021,270	0	0
British Red Cross Fund	5,830,036	0	0
Tobacco Fund	123,454	0	0

A Motor Cyclist's Enthusiasm.

Driver G. N. Bull writes from Egypt specially to refer us to the article which recently appeared in *The Motor Cycle* entitled from "Birmingham to the Isle of Wight," in which the author referred to the town of Brighstone as being pronounced Brigstone. Driver Bull tells us this is the old-fashioned way; it is now pronounced as it is spelt.

Light Cars for All Weathers.

Those interested in light and economical winter cars should buy a copy of next Wednesday's issue of *The Light Car*, which will be mainly devoted to the subject. Coupés of the limousine and cabriolet types will be dealt with in detail. *The Light Car* is an enterprising journal in a buff cover, issued from the offices of *The Motor Cycle* every Wednesday, one penny.

Expiration of Petrol Licences.

There has been a misunderstanding in the minds of some people respecting the validity of petrol licences after the end of April next. The Petrol Committee in a recent communication says that balance of petrol allotted but not purchased may be obtained any time after April. It is understood, of course, that not more than the maximum amount allotted to motor cyclists will be able to be purchased in any subsequent month.

Mr. Edge's New Appointment.

Mr. S. F. Edge, the well-known motorist, and a pioneer motor cyclist, who, since his retirement from business, has devoted his time to the study of agriculture, has been appointed Agricultural Machinery Controller. In the early days of the movement he was a generous patron of motor cycling, and even now takes a kindly interest in the pastime. He is a great believer in the lightweight.

An Illuminating Clause.

No lights are to be shown on stationary vehicles visible from the sea, yet no machines may be left stationary without lights in any place to which the public have access. The "dark" lamp would appear to offer the only solution.

From the "Birmingham Post."

"Wanted, motor bicycle, first-class only, 1916 B.S.A. or Triumph, only perfect one; £20 to £30.—Call ———." We refrain from giving full name and address, but if any reader is anxious to dispose of his 1916 Triumph or B.S.A. for that amount we will forward his letter.

The Ubiquitous Sidecar.

We notice the Imperial Tobacco Co., in a series of picture cards issued with cigarettes, speak of and illustrate the sidecar. "These handy motor cycles," the description goes, "with their sidecars, were quickly adopted by the military authorities as a very satisfactory means of rapid transit. All the allied armies are using these reliable and very efficient little machines, and large numbers of them are in constant use at the Front."

Flexible Rating.

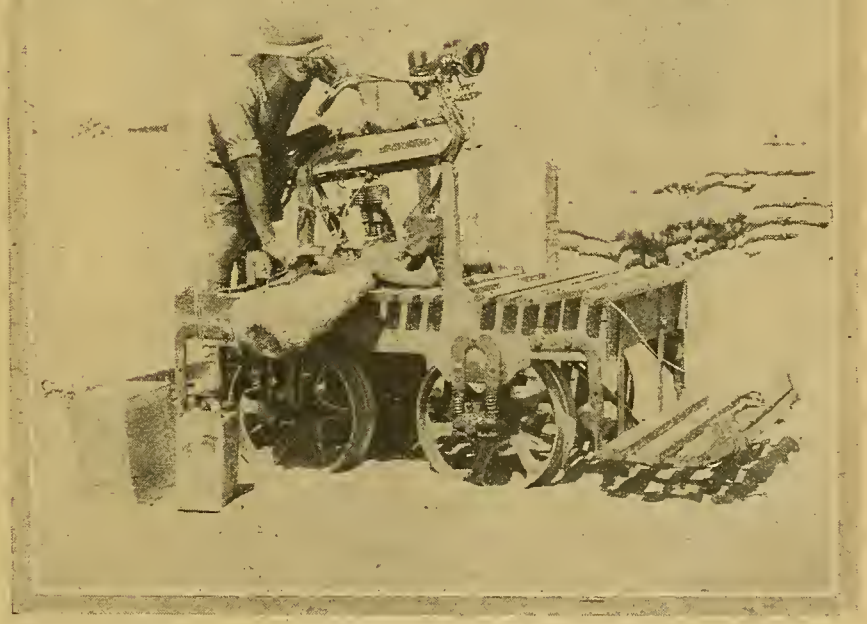
We have before us a private owner's advertisement from *The Motor Cycle* stating that he has a 17 h.p. Indian for sale. We do not aim at solving the question, but, judging from the latest rating of the big American twins (Harley-Davidson 16 h.p., Reading Standard 12 h.p.), he has probably heard the very latest news of the Indians *new* h.p., though we must acknowledge it has not yet reached us.

Army Motor Cycles.

The subject of recurring troubles with motor cycles in the Services is discussed, not for the first time, in our leading article this week.

The Human Body and the Motor Bicycle.

The other evening Professor Arthur Keith, M.D., F.R.C.S., opened a course of juvenile lectures at the Royal Institution. The first was entitled "The Human Machine, which All must Work." In the course of the lecture Professor Keith likened the 300 muscles of the human body to an engine, and said "that in some respects they are like the internal combustion engine of a motor bicycle; in other respects they are very unlike it." And with the aid of diagrams of both the motor bicycle and the human body he explained the resemblances and differences. "Muscles are slow combustion engines fitted with so perfect a radiatory system that they never become overheated." "Water," the lecturer went on to say, "has constantly to be applied to motor bicycle engines to keep them cool." Evidently the learned professor is more closely acquainted with muscles than motor bicycles. "Muscles are also furnished with sparking plugs—an ignition system—which rarely get out of order." The first motor bicycle engine had to do four strokes to get one effect. A pump was invented which did away with two of these strokes. "But millions and millions of years ago," Professor Keith said, "Nature saw the value of the pump for the human machine, and so she provided the heart." We are afraid that a motor cyclist would find this line of argument a little hard to follow.



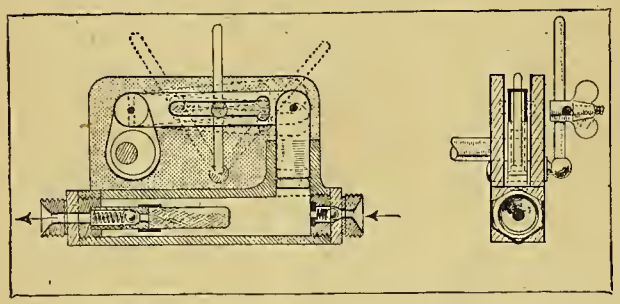
RAILWAY TROLLEY PROPELLED BY MOTOR CYCLE ENGINE.

The ingenuity of our fighting men at the various fronts is to be admired. The light railway trolley shown above in Western Egypt is propelled by a 4 h.p. Triumph motor cycle jury-rigged for the purpose. The turn of speed the trolley can attain is quite surprising. (*Passed by the Press Censor.*)

Throttle-controlled Lubrication.

A New Oil Pump combining Simplicity and Efficiency with a Minimum of Moving Parts.

IN the leader of our issue of December 21st last we again called attention to the extremely important subject of mechanical lubrication controlled in conjunction with the throttle, and we remarked that, "Though progress, so far as the ordinary riding public is concerned, may be comparatively slow, the fact remains that behind the scenes there is a good deal of experimental work quietly in progress." We had in mind several notable departures by well-known manufacturers, but we were



The Lamplugh throttle-controlled lubricator with cover removed, as fitted to a 3 h.p. Enfield for experimental purposes.

unaware of this, the latest throttle-controlled oil pump. It is the invention of Mr. J. S. Spittle, director and secretary of Messrs. S. A. Lamplugh, Ltd., of Tyseley, Birmingham, and is the outcome of several years' experimental work devoted to the question of perfect lubrication.

Positive Action.

Its principal feature is the positive up and down stroke of the plunger, obtained without the use of springs. A small gun-metal casting carries the whole mechanism; a flexible driving cable, driven from any suitable part of the engine unit, turns a worm and wheel; the shaft of the wheel carries a short crank, set eccentrically, so that a regular up and down motion is imparted. To the small end of the crank is pivoted one end of a lever, the other end being pivoted to the top of the pump plunger. This lever carries a movable stud, sliding in a slot in the lever, and operated by an outside rod. The Bowden throttle control cable is attached to this rod, so that the stroke of the pump is varied exactly as the throttle opening is varied. The range of stroke variation is from nil to $\frac{3}{16}$in., this being found sufficient for all types of motor cycle engines. The position of the cable attachment to the operating rod, whether high or low, can be adapted to give the best range of movement to suit a particular engine, and once set need not be altered.

The oil is passed straight through the body of the pump by means of inlet and outlet ball valves; a gauze filter is also provided. The plunger is solid metal with a cup leather head. A remarkable feature is that the whole pump is assembled without the use of nuts or screws, by means of a neat arrangement of slots in the casting. It can be taken down and reassembled very quickly without any special tools.

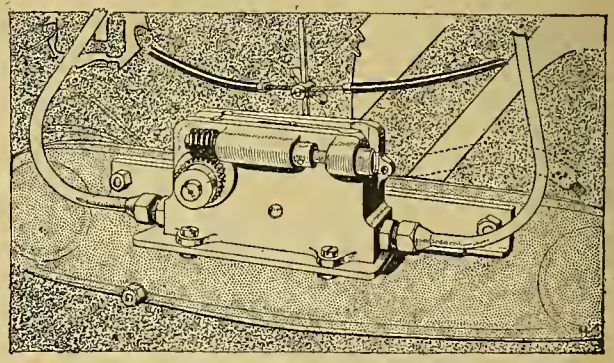
Easily Fitted.

The moving parts are enclosed by a detachable cover to exclude dirt. It will make no difference where it is fitted to the machine—the drive can be taken from any suitable point by flexible cable or other direct means, and once set to suit the engine the pump should need no further attention. There is practically nothing to get out of order, wear in its moving parts is negligible because it works very slowly, and if it is used in conjunction with a sight feed the action will be constantly evident to the rider.

Our illustration shows it, as fitted to a 3 h.p. Enfield twin for preliminary experiments; it was attached to the magneto chain cover and driven off the end of the magneto shaft. There is no doubt about its efficiency; with the engine running at half throttle or less, the sight feed was dripping regularly, and at full throttle the oil came through in big spurts practically amounting to a continuous stream.

Motor cycle manufacturers can be supplied with models for testing, and Messrs. Lamplugh will soon be in a position to undertake the manufacture in large quantities if required for Government purposes.

Its simplicity, positive action, easy fitting, and small cost should appeal to all, and we may predict, with confidence, that the time is not far off when all reputable machines will carry some such type of throttle-controlled lubricator as a standard fitting.



Section and end view of the Lamplugh pump. The dotted lines indicate the extreme movements of the control.

PROPOSED ASSOCIATION OF PRIVATE OWNERS.

AS it appeared desirable that a private owners' association should be formed, a small meeting was held recently to consider the question. A subscription of 10s. for car owners and 5s. for motor cyclists was suggested, and the meeting was adjourned until January 16th, when it will take place at 2.45 p.m. at the Bedford Head Hotel, Maiden Lane, Bedford Street, Strand. Admission will be by visiting card (name and full address), and a declaration must be signed that the visitor is in no way connected with the motor trade. Those intending to be present are requested to send a postcard to Maj. H. Vane Stow, secretary *pro tem.*, 353, Strand, London, W.C.

AVERAGE PRICES.

IN giving our usual list of second-hand prices we would draw the attention of our readers to the fact that these figures represent the approximate value of ordinary standard models. Machines with electric lighting equipment, etc., do not come under this heading, as, on the score of simplicity, the detailing of extra fittings cannot be included.

EXPORTS AND IMPORTS.

THE chief point of interest the current figures bring to light is that the export of motor cycles for 1916 shows an increase of 1,924 over the figures of the preceding year, but during 1916 more spares and unassembled parts were sent abroad than during 1915.

As regards imports, since these have been prohibited since last March, it is not surprising that only five machines, presumably commercial vehicles, have found their way into this country during the past month.

IMPORTS.

	1914.	1915.	1916.
MONTH ENDED DECEMBER 31ST.			
Number of Machines	52	217	5
Value of Machines	£1,721	£9,660	£210
Value of all Parts, Accessories, Spares, etc.	£2,604	£13,372	£8,526
YEAR ENDED DECEMBER 31ST.			
Number of Machines	2,559	4,531	1,192
Value of Machines	£93,121	£205,817	£50,478
Value of all Parts, Accessories, Spares, etc.	£94,540	£157,506	£125,537

EXPORTS.

	1914.	1915.	1916.
MONTH ENDED DECEMBER 31ST.			
Number of Machines	1,101	1,065	691
Value of Machines	£52,435	£57,845	£32,674
Value of all Parts, Accessories, Spares, etc.	£21,595	£32,700	£22,290
YEAR ENDED DECEMBER 31ST.			
Number of Machines	20,877	10,927	12,851
Value of Machines	£988,473	£510,374	£565,067
Value of all Parts, Accessories, Spares, etc.	£346,777	£311,372	£364,485

PETROL IMPORTS.

The petrol imports for December, 1915, exceed those of December, 1916, by 8,882,524 gallons, the figures being:

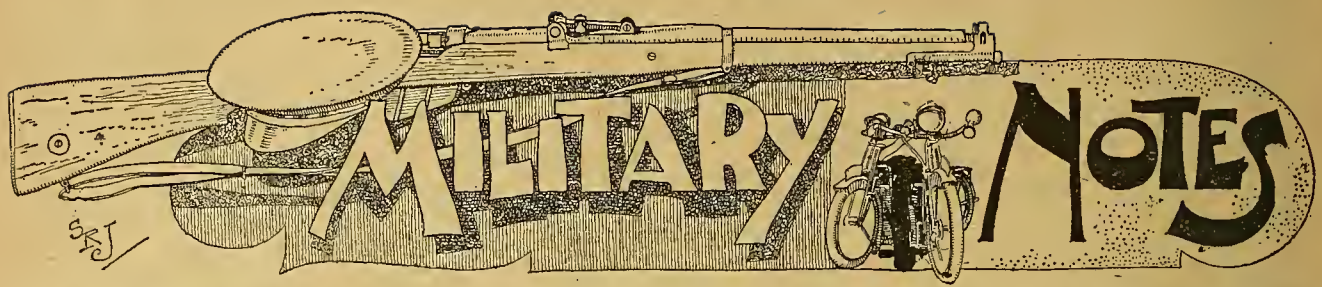
	Gallons.
December, 1915	12,983,382
„ 1916	4,100,858

Taking the whole year, however, the petrol imports are very much higher for 1916 than for 1915, the figures showing an increase of 17,239,875 gallons.

	Gallons.
Year ended 1915	144,574,891
„ „ 1916	161,814,766

THE AUTO-PED IN ENGLAND.

The Auto-ped has arrived, and its user was soon in trouble—not of the mechanical variety! Miss Shirley Kellogg, the revue actress, took her motor scooter for a spin and was hauled up for "causing an obstruction," so the daily papers say. Most likely, however, the absence of registration letters was the real offence, as the scooter is a motor cycle within the meaning of the Act.



THE CHAIRMAN OF THE AIR BOARD.

LORD COWDRAY, who has been appointed Chairman of the Air Board, is the father of the Hon. Geoffrey Pearson, who, when acting as a motor cycle despatch rider, was killed in France in 1914 during the retreat from Mons.

RACING MOTOR CYCLIST IN EGYPT.

WE have received the following interesting letter from Cpl. T. E. Greene, whom all will remember as the dashing Irish rider of Rudge motor cycles. It will be recollected that he is the holder of the Irish End-to-end record, and his daring riding in the T.T. races, in Spain, and other places will also be recalled. Greene is now serving with the A.S.C., M.T., in Egypt.

"I see so many letters and photographs reproduced in your valuable paper every week (as we even get it so far out as Egypt), that I thought I would take the liberty of writing a few lines myself. I am head motor cycle tester and finisher at the base repair depot for all Egypt, and I can tell you it is some job, too. We have to deal with all makes and dates of machines, and have not got the very best of roads for testing purposes. Alexandria itself is all that *pavé* stuff, not at all pleasant to ride on, and the natives seem to delight in walking in the roadway. We therefore have to do any testing outside the city itself, and there one finds most of the roads—if you can call them roads—in a terrible state, with about three to four inches of sand. The pot-holes, which are very deep, cannot be seen until close up, then one finds oneself nearly over the handle-bars owing to the crank case coming into contact with the ground. As a matter of fact, I have knocked several oil drain lugs out of the Triumph crank case owing to this, and the front stand clip of the Douglas being in the way, I always take the clip off now while testing. If the roads out here were anything like they are in England one could not ask for anything better than motor cycling, as the weather is the very best. There is no need to worry as to whether it will rain before you get back or not. We have been here now eight months, and have not had one night's rain in that time. How would that suit at home? All right for twenty-four hour runs, etc.? What?"

MOTOR MACHINE GUNNERS IN GERMAN EAST.

A MEMBER of a battery operating in British East Africa writes under date of November 7th last that the batteries are doing excellent service "out there," besides which there are a number of officers and N.C.O.'s from Bisley in the Gold Coast regiments. The writer, having recovered from malaria, was just in time to catch up his battery at Kondoa when Van Deventer moved to take the railway. This particular battery was the first unit to cross and cut the German central railway—another feather in the M.M.G.S. cap. A Douglas rider attached to the battery was the first to cross, two of the scouts, forgetting that they had been warned of mines, "scrapped" for the bridge, closely followed by armoured cars. At the time of writing, our informant was back at the workshops, having returned to have the back axle of one of the cars straightened. This is not the first axle which has required attention, he remarks, but never a motor cycle frame. The motor cyclists in German East Africa get any amount of rough riding, he adds with emphasis.

Cpl. T. E. Greene, A.S.C., M.T., E.E.F., testing repaired Douglas motor cycles on the rough ground in the neighbourhood of Alexandria. (See letter.)

FLIGHT-LT. GEORGE EDWARDS KILLED.

WE regret to record the death of Flight-Lt. George Edwards, who for some time was officially reported missing. He was associated with the motor cycling world for many years, and was one of the first to design a practical pillion-seat, a photograph of

which appeared in *The Motor Cycle* at the time of his attempt to place it on the market. After doing useful work as a despatch rider in Egypt, he joined the R.F.C., obtaining his wings after three months training.

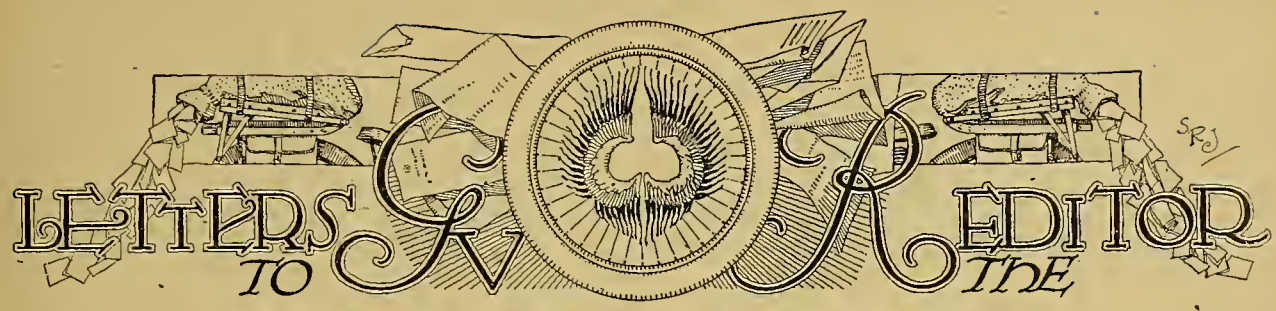
A FRENCHMAN'S APPRECIATION.

IT is not our usual practice to publish appreciations of *The Motor Cycle*, owing to lack of space, but we cannot refrain from repeating a quaint paragraph of appreciation received from an officer in the French Army:

"Your very marvellous paper *The Motor Cycle* is my sweet companion in the first line, and I read it with very great pleasure. I hope you will have a good 1917 year."

MENTIONED IN DESPATCHES.

AMONG the 3,040 names of those mentioned in despatches, we note those of Capt. A. E. Davidson, R.E., D.S.O., whom we announced as having recently been promoted to the rank of Major, motor cyclist Cpl. W. Bailey, artificer motor cyclist Cpl. J. Brand, and motor cyclist Cpl. W. J. Scarff. Temp-Lt. C. J. Cadman, R.E. (Special Reserve), who was a motor cyclist with the first Expeditionary Force, has been awarded the Military Cross.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

NORTON ENGINES.

Sir,—An absurd rumour is being spread by someone, which seems to be gaining ground, for it has reached us from many parts of the kingdom, and appears to have become fairly prevalent at the Front, that we are now using another make of engine than our own (the Norton) for our machines. May we through your columns most emphatically contradict this? *The Norton original long stroke engine, designed and made by ourselves, is the only power unit ever fitted to Norton motor cycles*, and we have no intention of fitting another make at any time.

NORTON MOTORS, LTD.

AN UNUSUAL TROUBLE.

Sir,—*Re* your paragraph (January 4th, page 11), I had the same thing happen last year. The machine was an American Excelsior, the fastest and most comfortable riding machine I have owned, and I have had forty-two. This was caused through a slight seizure at over 70 m.p.h. After the engine had cooled it was perfectly free, but after about another four hundred miles an oil leakage was noticeable, which I took to be the union on front cylinder oil feed. This went on for about six weeks, and then the cylinder came in two. The makers replaced this free of charge, however. C.E.T.

Bedford.

HOW TO CLEAN A CRANK CASE.

Sir,—Some weeks ago I saw a letter in *The Motor Cycle* from a correspondent who wished to clean his crank case and had used a strong solution of soda for the purpose.

Sodium in any form will discolour aluminium, and should not be used if the colour is to be kept good. Scrub well with a wire brush and paraffin, and then wash with a little petrol. You may then wash with a very little *soft* soap (which is not a sodium but a potassium soap), and paint over with a fairly strong solution of magnesium, such as ordinary liquid magnesia or sulphate of magnesia, commonly called Epsom salts, which will (or ought to) restore the brilliant white colour to the metal.

H. H. BROWNRIGG.

THE SCOTT SOCIABLE.

Sir,—I have for some few years been a very interested reader of *The Motor Cycle*, and would be very sorry to get out of touch with the movements of the motor cycling world, although I have never yet owned a motor cycle.

I think that Mr. Scott deserves a "pat on the back" for putting his invention before the public. His motives are clearly seen, viz., simplicity and economy. Many motor cyclists would not ride motor cycles if they could afford cars; hence the introduction of the sidecar. The sidecar has the advantage of being easily and quickly removed, but what about the driver in wet weather? The Scott Sociable, whilst being an unalterable two-seated machine, would be far and away more comfortable to at least the driver, if not the passenger, to say nothing about the protection from the elements.

Then, again, take the consumption and the tax, both of which would be about the same as any big twin combination. If the sociable were a trifle more extravagant, would not the extra comfort and protection over-balance its so-called ugly appearance?

I have no connection whatever with Mr. Scott, and, as far as I know, have never seen him, but I must express my gratitude to him (through your paper, if you will permit) for introducing such a handy, accessible, sensible, and economical machine as the Scott Sociable, and I may say that if all goes well, after the war, I shall see about purchasing one. HAROLD E. CARTWRIGHT.

WATER INJECTION IN A PETROL ENGINE.

Sir,—I note a letter on the above subject in *The Motor Cycle* of December 7th, signed "L.G. (R.N.)," stating that "the idea of introducing water into the cylinder of his engine was patented by Prof. Banco in Germany some years ago." As this statement is inclined to be considerably misleading, and also as the question of water injection appears to be considered something of a novelty, the following points may be of interest.

It may be said at once that the idea of water injection dates back to the earliest stages of the conception of the gas engine. Reference to "The Gas Engine Manual," by W. A. Tookey (a well-known writer on internal combustion practice), records the following instances of its use:

First, as far back as 1791, by John Barber, in an attempt to make a gas turbine; later in reciprocating gas engines by Samuel Brown, in 1823; by Hugon in 1865; and by Brayton in 1873; water being introduced partly, of course, for cooling purposes, but also for the purpose of attempting to combine the use of steam and gas expansion. Further than this, water injection has been considerably experimented with by gas engine makers in more recent times, particularly in attempts to obtain practical advantages from very high compression pressures.

The use of water injection also became quite common practice with oil engine manufacturers, compression being carried to a point where ignition became spontaneous, the actual timing of the ignition being carried out by water injection of varying amounts to suit the load prevailing; but latterly this practice has been dropped, a point of makers' advertisements being, "No water injection"! Evidently there is a fly in the ointment!

Water injection would appear to give numerous advantages, and actually does so; but, unfortunately, it brings attendant with it disadvantages that more than counteract any gains. The disadvantages follow, firstly, from the fact that water always contains impurities, which, when water is turned into steam, are left behind, forming a hard deposit on cylinders and valves, causing cutting of valve faces and endless trouble; secondly, most fuels contain a small percentage of sulphur, which, released on combustion of the fuel (my knowledge of chemistry is somewhat "rocky," but I believe this statement is *au fait*), combines with water vapours to form sulphuric acid, causing considerable corrosion to valves and exhaust connections. Perhaps some of your readers can give us valuable information on the chemical action taking place, and possibly also give us a chemical analysis of petrol and other motor fuels.

It will be seen, however, that the introduction of water into the cylinder of an internal combustion engine is attendant with difficulties which must be overcome before success is attained. Reference to periodicals and treatises on internal combustion engineering will often give much valuable information and save a good deal of "spade" work to motor cyclists who have the opportunity to experiment.

The principles involved in gas and oil engines are, of course, the same as in petrol engines, though proper consideration would need to be given to the different circumstances under which a motor cycle engine is required to work. W.M.

Workington.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—I cannot let the two subjects at present under discussion, viz.; "Flat Twin *v.* Single" and "British Twin *v.* American Twin," slip past without saying anything. To those who contend that it is impossible to build a well-designed frame for the flat twin I reply that it is not only possible, but has been done. I admit, nevertheless, that some flat twins have not well designed frames. How a good flat twin engine can be expected to keep vertical in the frame, when it is only attached to lugs on the bottom tube, I do not know, and, in a good many machines of this type that I have seen, it has not remained upright, but has pulled itself over on the driving side. Another thing which puts me off the average flat twin is the ceaseless rattle, which seems to come mostly from the timing gear.

Sporting single every time for me, except for sidecar work!

Now for the Americans.

Have any of your pro-American correspondents tried to bore holes in the American radiating fins? They will find them to be made of stuff as brittle as glass. How many of these people, who say the American has the most silent timing gear, have ridden an A.J.S. "6"? This machine has quite the most silent timing gear on the road. Usual disclaimers in large quantities.

H. ST. V. ADDENBROOKE.

Sir,—Perhaps Mr. Granville Bradshaw and "R.E.C." will modify their views that a long induction pipe does not affect carburation. I refer them to "Ixion's" tale of horizontal woe on page 553 of your issue of December 28th, 1916. His "paradox" was merely overheating due to running on an unduly bad (probably very weak) mixture. The low temperature of his long induction pipe caused condensation of the petrol on the walls of the pipe, and the resultant mixture was not at all satisfactory for running on. When sufficient fluid petrol had run into his hot inlet port and was vaporised by the heat, the temporary enriching of the mixture gave him his momentary acceleration. Lagging the pipe proved to be the cure. Precisely! His experience (I admire his fairmindedness in publishing it) comes at a very awkward moment for those who are trying to persuade us that long exposed induction pipes are an advantage. My experience this winter with a horizonal twin is precisely the same as "Ixion's," and my carburetter is *exhaust jacketed*.

Finally, if an engine can indulge simultaneously in an overheated sparking plug and a refrigerator inlet pipe, what constitutes a "hot side"?

Further in answer to "R.E.C.," the paragraph on flat twins in my article of December 14th does not apply solely to the Douglas or to any other individual make, but applies to all the flat twins I know of.

If long exposed induction pipes do not mean bad carburation, then all the tendency of modern car engine design is wrong.

I have had as much trouble out of a horizontal twin in a month as I get out of a single in a year. I mention no names.

A. LINDSAY,
CAPT. R.A.M.C.

THE FLAT TWIN AT THE BAR.

Sir,—I have read Mr. de Lissa's comments on the A.B.C. and its designer, and I should like to say a word or two in reply.

Mr. Bradshaw's sketches in the previous issue are clearly his own engines, therefore I fail to see how Mr. de Lissa can accuse Mr. Bradshaw of criticising other people's designs.

Re the "hot top" and "hot side." Could there be anything much worse than an unequally expanding cylinder? And this is what a "hot side" generally means. Personally, I shall be pleased to see some of Mr. de Lissa's shading, and then we shall see where the abnormally "hot top" comes in. To my mind, the position of the A.B.C. exhaust port and valve is very good. The valve must be cooled by the incoming charge, also the position of the exhaust exit lends itself to efficient cooling. At any rate, it is not stuck on the cylinder side, which would again give us a "hot side."

Mr. de Lissa's remarks about plug electrodes do not apply to A.B.C. engines so far as my experience goes. I used one of these engines with overhead valves in the 1913 T.T. and the practice of the 1914 race; my only plug trouble was through over-oiling. I have, however, experienced on Brooklands (with a well-known side-by-side valve single) the plug drooping trouble, also plugs blowing out, cylinders warping, etc.

Mr. de Lissa speaks as though 5,000 engines is a tremendous number. It would be interesting to know how many engines the A.B.C. Co. have turned out (probably it would be censored). Regarding the "rude shocks," all I can say is "wait and see," but in the meantime do not forget the A.B.C. was the first machine (500 c.c.) to do over 80 m.p.h. I also wonder how much credit was given to Mr. G. E. Bradshaw for the performance of a well-known flat twin when it broke the kilometre and mile world's records in the 350 c.c. class, and how much he designed and made.

Naturally, Mr. de Lissa calls a clever designer a man who designs an engine like the M.A.G. I do not blame him. I, as an uninterested (financially) auto engineer, consider a man who can design a power unit like the A.B.C. not only a designer, but one who knows his job and understands metallurgy.

Mr. de Lissa cannot see why such a wonderful and powerful engine as the A.B.C. *is* should require a four-speed box, and mentions A.B.C.'s claim to 4 to 70 m.p.h. on top. Well, what an engine is capable of doing and what (in time) it would take out of the transmission, engine, and tyres, entitles a designer to give us a four or even a six-speed box, provided it is a properly designed gate change. Whilst on the subject of gear boxes, I should strongly advise several designers (both car and motor cycle) to examine an A.B.C. and try and find out how it is that a perfect change can be made under almost all conditions.

Probably Messrs. Rolls-Royce will tell Mr. de Lissa the necessity of their fitting a four-speed box to their splendidly balanced, vibrationless, six-cylinder engined car.

Yes, as your letter says, Mr. de Lissa, the A.B.C. engine is quite good—in fact, it is better designed than anything yet manufactured in the motor cycle world, and most certainly the best engineering job.

ALF. WRAY.

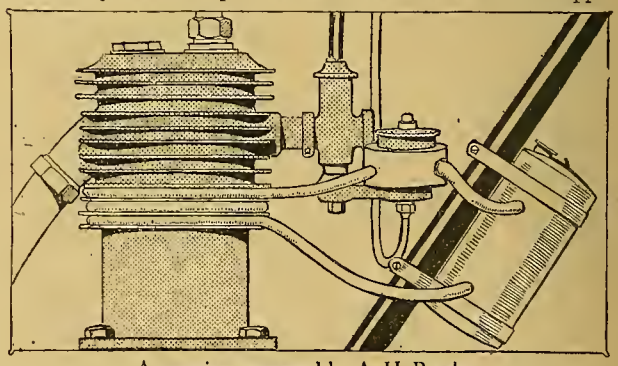
A CURIOUS CASE.

Sir,—In reply to "A Curious Case" sent by Cyclist H. J. Ives (2581), I may state I had similar trouble with a 2¼ h.p. New Hudson. What I found to be the trouble was the magneto cog had slipped back a little, and the ignition became too far retarded. I tried various settings of the magneto, and found I got the best results with the magneto giving the spark when the piston was threequarters of an inch from the top (on compression). The engine will now take all the air I can give it, climb all hills on top, and never blows back.

T.C.
Falkirk.

ANOTHER SUGGESTED VAPORISER.

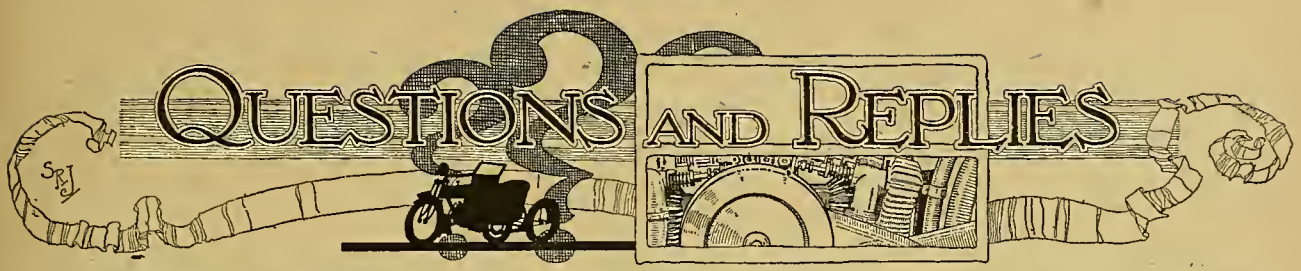
Sir,—Having read a lot of suggestions in *The Motor Cycle re* vaporising, I enclose a sketch of an appliance for vaporising petrol substitutes or paraffin. The water is circulated by the thermo-syphon principle. The engine can be started on petrol and turned on to the substitute when it is sufficiently warmed up. The carburetter is set into a copper



A vaporiser suggested by A. H Burslem.

cup, forming a water jacket round it. A small can containing water could be put conveniently on the frame, with a pipe round the flanges of the cylinder to the carburetter water jacket and a pipe from the carburetter water jacket back to the water tank, and so complete the water circulation. I have not tried this idea, but I think it is a suggestion for vaporising substitutes.

A. H. BURSLEM.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Charging from Magneto.

I have a high-tension magneto off a 3½ h.p. machine, and am wanting to use it for charging an accumulator, if possible. Will you please let me know if this can be done, and also how I must connect them in order to do so successfully?—G.W.

It is not in any way possible to charge accumulators from any kind of magneto. The current given by any magneto is alternating, and is, therefore, quite unsuitable.

Generator Trouble.

On a recent night I had a ride of about twenty-six miles; there were 8° of frost and a very cold wind. About half-way I was troubled with a poor light (acetylene), which finally went out. I found a good deal of water in the tubing, which is fairly long, as I light the sidecar and tail lights from the generator. After emptying the pipes I was twice troubled with the same difficulty. I have recently fitted a length of copper tubing; this is my worst experience of water in tubing. Would moisture in the carbide condense on the copper piping in the cold and cause this quantity of water? It was cold enough to freeze the water in the generator while waiting. The other morning there must have been teaspoonfuls of water in the piping, in spite of emptying the pipes three times the previous night. I am inclined to fit a rubber gasbag at the lowest point of the tubing to catch any water which may collect. I took the generator down: the filter pad was damp, but not wet.—H.E.N

We have never heard of water condensing in the copper pipe used for acetylene gas lighting. This, we think, is more likely to be water which reaches the pipe through a fault in the generator, or from some outside cause, or through your generator at some time having been flooded. Perhaps the gas orifice is partially stopped up. See that all the orifices in the generator are quite free, and that the generator is scrupulously clean in every part. Fill your container only two-thirds full, and we do not think you will suffer from this trouble again. In very frosty weather it is advisable to leave the generator empty, and only fill up just before you require the lamp, and then with tepid water. When once the lamp has been lit the generation of the gas in the generator gives heat, and this prevents the water from freezing. Take out the filter and dry it.

Difficult Starting.

I have a 2¾ h.p. V twin motor cycle about three years old. In the cold weather I find it extremely difficult to start. I inject plenty of petrol into the compression taps, but then it takes me about fifteen minutes to start it by pedalling, even if I put more petrol in the compression taps. I should be very much obliged if you could give me a little advice.—L.C.P.

The most usual causes of difficult starting are as follow, and we think if you check all the items given you should be able to overcome the trouble: (1.) Partially choked jet. (2.) Air leaks between the carburetter and inlet ports. (Bind all doubtful joints with insulating tape.) (3.) Contact breaker points not breaking or making contact properly. The points should be clean and flat, and separate .4 mm.—roughly, the thickness of a visiting card. (4.) Plug points should be clean and free from oil, with a gap of about $\frac{1}{32}$in. (5.) See that the magneto generally is in good order, carbon brushes clean, and making good contact. (6.) See that the valves are closing properly and the valve springs strong enough. Clearance between the tappets should be .4 mm. To start, prime the engine with petrol in each cylinder to free the pistons, flood the carburetter, close the air lever, and open the throttle about a quarter. What is wanted is a strong mixture, and only a little of it. If still difficult, cut down the main air inlet.

A Herald of Spring.

Tyre Arrangement.

I have a 6 h.p. sidecar combination, and am going to rearrange the tyres as follows. An extra strong new cover for the back wheel. The tyre from the back wheel to be put on the front wheel, and the front wheel tyre to be put on the sidecar wheel. The back tyre has a fairly good tread on it, but the front tyre is worn pretty level, though is still a good cover. Would this arrangement be best, or would it be better to fit the tyre from the back wheel to the sidecar wheel, or is it necessary to have a good tyre on the sidecar? If so, would the front tyre do for the sidecar if I had it retreaded?—BC 1818.

The arrangement suggested is excellent. The wheel which has the easiest time of any in a sidecar combination is the sidecar wheel. It does not much matter which you put on this, provided it is fairly good. Retreading is rather a lottery.

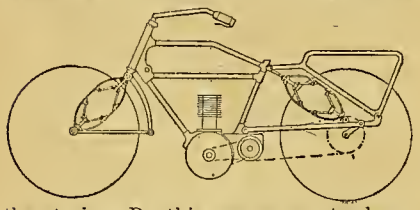
A Case of Late Timing.

I should be obliged if you could give me some advice about my cycle. It is a 2¾ h.p. Douglas (1913). Up till a short time ago I could run with the extra air lever fully open and control speeds with the throttle. Now the machine runs excessively noisily, and has no speed. When the throttle is opened the engine only vibrates heavily. It will take hardly any extra air, and cannot be throttled down at all without shutting out air altogether. On the road if I open the air suddenly the machine leaps forward for about fifty yards, and then coughs and splutters and I am forced to shut off the air. I have ground in the valves, and compression is all right. Could you tell me where the crank case release is on this machine? The jet is quite clear. Amac carburetter.—E.N.G.

The symptoms suggest that the timing of your magneto has slipped. Retime the ignition, and make sure that both the magneto sprocket and the driving sprocket fit properly on their respective shafts. See that both main jet and spraying jets are quite clear, and that petrol is flowing freely from the tank, and also through the passage to the jet. At this time of year it is important that all air drawn into the carburetter should be heated in order to prevent freezing in the carburetter or induction pipe. The crank case release valve is through the hollow crankshaft into the timing case.

A Springing System.

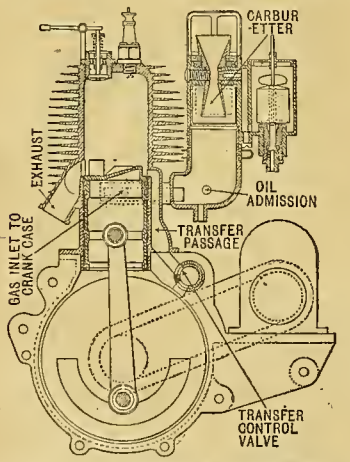
The feature of novelty is the arrangement of two leaf springs in the form of an ellipse, combined with link work, which distributes the strain throughout the length of the springs. The drawing shows back and front suspension, and in both cases it will be seen that movement of the wheel spindle tends to distort the elliptic springs. At the same time the link work is compressed in one direction and expanded in the other, increasing the resistance to movement and distributing



the strain. By this means any tendency for the springs to distort excessively at any one point is prevented, and breakage avoided.—W. J. Simpson, No. 143,931, 1915.

An Italian Two-stroke Engine.

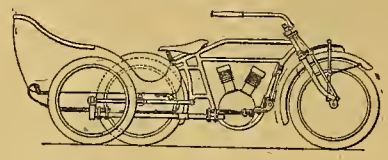
In this engine the charge is initially compressed in the crank chamber, and then passes to the cylinders by way of a transfer passage. The transfer passage is formed with a cylindrical enlargement in which is a rotatable sleeve whereby the passage of the mixture from the crank case to the cylinder can be controlled. The exhaust port is of the usual kind, and the inlet ports, which put the carburetter into communication with the crank case when the piston is at the top of its stroke, are elongated to present a large area of opening. The carburetter is

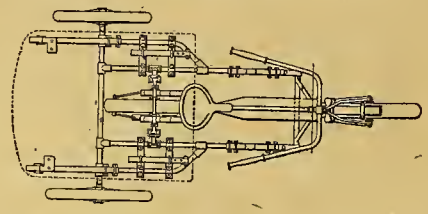


arranged in a chamber alongside the cylinder, and oil is led to this chamber so that it reaches the mixture just before it enters the crank case.—D. Ruva, No. 101,251.

A Trailer Attachment.

In view of the fact that a device of this nature is meeting with a certain measure of success in America, the accompanying elevation and plan of a rear passenger attachment may be of interest. The "rear car" is provided with an axle tube, from which project forwardly a pair of

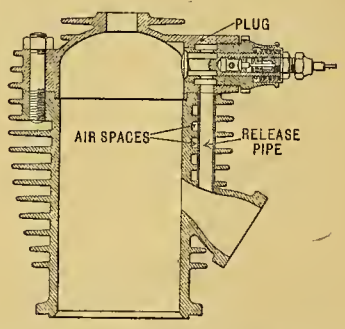




longitudinal members. These extend on either side of the motor cycle, and are connected through laminated springs with the frame just in front of the engine. The "rear car" body is mounted on its frame by means of springs, so that it is insulated from road shocks. The specification describes and illustrates the invention in great detail.—O. L. Heintz, No. 16,055, 1915.

Compression Release Mechanism.

The feature of this invention is the employment of a loose pipe for conducting the gas from the combustion chamber to the exhaust passage, when the control



valve is opened. The radiating fins are drilled through and the pipe inserted, the upper aperture then being plugged. An air space is left around the pipe as shown. The invention is not restricted to engines having a detachable cylinder head.—Villiers Engineering Co., Ltd., and G. Funck, No. 102,002.

DELAYS IN POSTAL DELIVERIES.

In view of depleted staffs, the curtailment of railway services, and the consequent delay in delivery of mails, readers will greatly assist by forwarding communications (including advertisements) as much as possible in advance of the dates of the issues for which they are intended.

Generosity to Soldiers Appreciated.

A gunner in the Tanks writes in appreciation of the action of the Austin Motor Co., Ltd., Prince of Wales Road, Norwich, in allowing soldiers to garage their motor cycles free of charge.

A Motor Ambulance.

The staff of the Far Eastern depots of the Asiatic Petroleum Co., Ltd., has presented a motor ambulance to the British Red Cross. The ambulance is well equipped, and capable of carrying four wounded soldiers.

Burberrys Sale.

The well-known firm of Burberrys are still holding the sale which began on January 1st of both men's and women's garments of every kind and size suitable for both winter and summer riding. Much of the stock is to be sold at one-half, and in some cases less than half, current prices. Readers are advised to write to Burberrys, Haymarket, London, S.W., for their sale list.

Lodge Sparking Plugs.

We have received from the Lodge Co., Ltd., Rugby, a useful brochure dealing with twenty differently designed plugs of their manufacture. A chapter entitled "How to Choose a Sparking Plug" is of particular interest at the moment. High speed and high compression engines are frequently fitted with plugs more suitable for low compressioned sidecar outfits, and in consequence grumbles at the efficiency of plugs are only too frequent.

Comfort Motor Cycle Accessories.

Kumfort accessories for motor cycles are fairly well known to our readers, having been referred to in these columns on several occasions. These products will in future be known by the ordinary spelling of the name. The company should now be addressed, "The Comfort Motor Cycle and Accessories Co., Cookham, Berks."

The Sphinx Plug Range.

The Sphinx Manufacturing Co., of Birmingham, makers of the well-known Sphinx plugs, have issued a most attractive catalogue and price list of their plugs, a very large range of which is described and illustrated. This publication has been much delayed owing to shortage of labour, but all applications for the booklet are being executed as quickly as possible and in strict rotation. Among the plugs illustrated is a new model designed specially for use in two-strokes or in engines which are inclined to be oily. The electrodes are protected from oil by shields.

Bowden Wire Ltd. of London

Manufacturers of Bowden Wire and of all Levers and Accessories used in its application.

Established 1897.

READ!

MY 3-PHASE JET DAMPING CARBURETTERS

have such perfect vaporising properties that they enable you to use fuel at **1/10** per gallon in 42-gallon casks, which you are allowed to keep on your premises. Casks **12/6** each, returnable at **10/-** each. Your engine will tick over dead slow, and pull dead slow in traffic, yet give the full power. It is almost impossible to tell you are not running on petrol at **3/-** a gallon. It cannot damage your engine or soot it up, and makes Motor Cycling possible in these times.

I give you my personal assurance of the truth of what is stated above. Please send at once for full particulars of the carburetter, and also for my Treatise on Carburation, and terms of One Month's Approval Trial.

C. BINKS, Ltd., Eccles.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed ——— & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. ooo, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

A.B.C.

A.B.C. for Sale, 1914, in fine condition, lamps and speedometer, new tyres.—Box 615, c/o *The Motor Cycle.* [X4144

Abingdon.

1914 Abingdon, 3-speed, T.T. model; £34.—Ross, 86, High Rd., Lee. [6786

GET IT AT TAYLORS

"A Happy New Year to our Friends at Home and at the Front."

We feel it opportune to send a few extracts from letters received from our clients at Home, from the Front, the Navy, and the Colonies during the past year.

We trust it will help to promote confidence to "GET IT AT TAYLORS."

Tidworth,
30th September, 1916.

Sirs,—I have to thank you for the prompt reply and supply of goods. You are the first motor accessory supply firm that I have as yet found who take the trouble to reply per return.

Here, away from all sources of supply, it is highly desirable to be able to get certain types of accessories per return.

I want three more of your catalogues—two for colleagues and one for this mess. Six or eight of us have machines.

Hendon,
22nd December, 1916.

Dear Mr. Taylor,—Many thanks for your letter enclosing account and for getting the chassis off so promptly. It is a pleasure to deal with a firm where promises are kept in these times.—H.B.

B.E.F.,
15th June, 1916.

The wheel arrived safely and promptly, for which I thank you. Your firm is the only one which seems to consider the interests of their customers, and your promptness in carrying out orders makes it a pleasure to deal with you.

Yours faithfully,
Major ———

Sturminster Newton,
27th July, 1916.

The speedometer is now working satisfactorily. In conclusion, may I express my keen appreciation of the very impartial manner you have dealt with this matter.

May you enjoy all the success you deserve, as firms such as yours are not to be met every day of the week; in fact, one in a lifetime is all one gets, and then they consider themselves lucky.

Again thanking you, and no doubt we shall do business in the future.

Yours faithfully,
C.S.T.

S. Africa,
5th June, 1915.

Dear Sirs,—The goods arrived in good order and condition, for which many thanks.

I am particularly pleased with the mechanical horn. It is strong, and has a fine note of warning—not jarring to the nerves, as is usual with other makes.

Yours faithfully,
C.H.H.

S. Africa,
11th September, 1916.

I am well pleased with the mechanical horn and Marvel vulcaniser received a few months ago.

Yours faithfully,
C.H.H.

Grand Fleet,
19th January, 1916.

Dear Sirs,—Goods received from you very satisfactory and on top line. Lamp arrived safe, with postal order covering balance.

I remain,
Yours truly,
G.S.B.L.

Beldam Retreads

THE easiest way to save money is to have a Beldam Retread instead of a new tyre—as long as the canvas is good. The cost, comparatively, is trifling, and you get thousands of extra miles—possibly more than from the original tread. Send old covers to us and we will quote you. The Beldam Tyre Co., Ltd., Brentford, Middlesex.

MOTOR CYCLES FOR SALE.

Sun.

RIDER TROWARD, 78, High St., Hampstead.—1915 Sun-V.T.S., 2-speed, perfect; 24 gns. [6968

COLMORE Depots, Birmingham and Manchester, for delivery from stock of all models of Sun motor cycles. [0807

SUN-VILLIERS Model de Luxe, 2-stroke, absolutely new; sacrifice £25.—108, Runcorn Rd., Moseley, Birmingham. [X4063

Sunbeam.

E. KICKHAM, Stokes Croft, Bristol.—1915 3½h.p. Sunbeam, all accessories, just overhauled; a bargain, £55. [X3926

1915 3½h.p. 3-speed Sunbeam Combination, fully equipped, excellent condition; £80; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0862

1914 3½h.p. Sunbeam with coachbuilt sidecar, all in fine order and condition; £52/10; deferred payments or exchanges.—Jones, Garage, Broadway, Muswell Hill. [7092

1916 3½h.p. 3-speed Sunbeam, 2 Lucas lamp sets, mechanical horn, Dunlops, ridden under 1,000 miles, condition guaranteed; £75.—Robinson's Garage, Green St., Cambridge. [7059

SUNBEAM, late 1914, 6h.p., luxurious Gloria sidecar, 5 attachments, speedometer, 3 lamps, horn, watch, all exceptionally fine condition; £80, near offer; after 7.—S., 54a, Redcliffe Sq., Earl's Court. [X4148

1916 7-9h.p. M.A.G. Sunbeam Combination, very little used, in perfect condition, hood, screen, lamps, speedometer, and spare wheel and tyre; £125, or exchange.—Colmore Depot, 211, Deansgate, Manchester. [6891

SUNBEAM, 1914 (late), 6h.p., 3-speed, lamps, horn, speedometer, with Burbury sidecar, special chassis, adjustable wind screen, good condition; bargain, £82.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C. [0492

SUNBEAM, 3½h.p., 1916, for sale, semi T.T. handlebars, new spare inner tube, lamps, speedometer, etc., very little used, perfect, Russian War Office model; will accept 70 gns. for quick sale.—Apply, J. Weiner, 32, Shaftesbury Av., W.C. [6854

3½h.p. 1915 Sunbeam and De Luxe Sidecar, fitted with Lucas lighting set, tools, a complete up-to-date combination, condition absolutely as new, including finish and mechanical parts and sidecar, handsome turnout, ready for the road, and fully guaranteed; 80 gns.—Wauchope's, 9, Shoe Lane, London. [6942

Swift.

SWIFT, 3½h.p., 1911, with light sidecar, powerful engine, excellent running order, good tyres, small mileage, decompressor, Multi pulley, accessories; £22.—Pearson, Wayside, Monmouth. [X3930

T.D.C.

3½h.p. T.D.C., with Armstrong 3-speed gear and free engine, and all latest fitments, with coachbuilt sidecar, in good condition; cheap.—46, Moss Lane, Bramhall, Chesbire. [X4121

Torpedo.

TORPEDO-PRECISION 2-speed Lightweight, recently overhauled; £16/10.—Motor Exchange, Horton St., Halifax. [6676

Triumph.

1913 Triumph and sidecar, 3-speed; £35.—Ross, 86, High Rd., Lee. [6790

TRIUMPH, 1911, clutch, nice machine; £20.—11, Luna Rd., Thornton Heath, S.E. [7027

3½h.p. Triumph, clutch model, in fine order; £20, no offers.—14, Dodbrooke Rd., W. Norwood. [0874

TRIUMPH, clutch model, 1914; first £25.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [6691

TRIUMPH Junior, equal to new condition, tyres and accessories likewise; 30 gns.—Bunting, Harrow. [6774

3½h.p. Triumph, clutch model, perfect condition; £24.—Apply by letter, Oaklea, Cheapside, Woking. [7035

TRIUMPH, 3½h.p., hand clutch, perfect condition throughout; 12 gns.—245, Hammersmith Rd., London, W. [6907

TRIUMPH, 1912, 3½h.p., clutch, excellent condition, with lightweight sidecar; £25.—Fortin, Stapleford, Cambs. [X4097

TRIUMPH, 3½h.p., 1912, plate clutch, good tyres, good order, and fast; £19.—14, Dodbrooke Rd., West Norwood. [0873

TRIUMPH, T.T., 3½h.p., late 1910, with Lucas lamps; £19/10.—Bentley, Medcalf Rd., Enfield Lock, Middlesex. [X4089

BABY Triumph, very good condition, engine just overhauled by makers, lamps, etc.; £32.—Bull, St. Giles' Sq., Northampton. [X4130

1908 Triumph, 3½h.p., Bosch, B. and B., grand order; ride reasonable distance; £15.—Howe, 9, Broughton Rd., Ipswich. [6798

TRIUMPH, 3½b.p., 1912, free engine, perfect condition, £24; sidecar, £3/10; appointment only.—21a, Broadway, Stamford Hill. [7017

LATE 1914 3-speed Triumph, with Montgomery sidecar, fully equipped, and as new, done 2,000; £47/10.—20, Whitley St., Reading. [7110

Second-hand Prices after the War.

AS is generally known, at the present time second-hand motor vehicles are commanding highly inflated figures, in many cases in excess of their original cost two years ago. These remarks apply to both the motor cycle and motor car worlds, but more forcibly still to light cars. With the prospect of a reasonably early peace, one is led to wonder how these figures will be affected when the manufacture of motor vehicles is resumed. Will prices drop suddenly and appreciably? Certainly there will be a drop in prices, but whether that drop will be considerable or not seems to depend upon the space of time it will take manufacturers to regain their normal stride. Some consider that there will be a sudden and appreciable decrease in the values of second-hand motor vehicles, but against such a possibility we have to consider that just as there will be an increased supply of motor cycles when peace returns, so also there will be a corresponding increase in the number of buyers. Which will outpace the other is the question. In this connection it may be remarked that there are thousands of men in the Army with sporting proclivities, who in many cases have a nice little sum in the bank. Their Army pay alone—which they are unable to spend by reason of their environment—will in many, many cases be more than sufficient to purchase the finest motor cycle. The temptation, increased by pent-up strain, will be for returned soldiers to enjoy themselves, and the first thought of men used to open air life is touring, or, at any rate, trips into the country.

To all such, motor cycles will make a strong appeal, and these facts, in conjunction with the great probability that it will take many months for manufacturers to reorganise their works and obtain the necessary amount of raw materials in order to resume their staple trade, will, to our mind, prevent any sudden or serious drop in the value of second-hand machines. In other words, normal peace state will not be resumed for a long time after the guns have ceased fire. One must remember, too, that one of the effects of this war has been to cause people to economise in every possible direction; thus it is extremely likely that those who formerly owned larger vehicles will be satisfied with a smaller and cheaper vehicle, and consequently all forms of economical motors will prove a distinct attraction.

Disposal of War-worn Machines.

The point we have raised is not a new one, but it vitally affects many thousands of our readers. In discussing the subject it has often been said that the anticipated release of thousands of motor vehicles by the Army will affect the issue. Government departments can, however, be relied upon not adversely to affect an industry by any rash or sweeping measures of this kind.

It is hardly likely that the war-worn vehicles which are at present rendering yeoman service to our Army will be available for distribution, even if the Government decide to dispose of them by auction, for some months after the end of the war, so that the threatened slump in second-hand values which many imagine will be produced by the sudden disposal of thousands of Army motor vehicles need not, at any rate, be expected immediately peace is declared. For one thing, transport facilities may not be such that motor vehicles can be returned immediately in any numbers, and Army decisions of this kind necessarily take time. Apart from this, is it a certainty that motorists will seize the opportunity to purchase vehicles regarding the history of which they know nothing? Keen buyers know that Army motors frequently receive gross ill-usage, and their work necessitates traversing roads and performing feats which test the parts almost to breaking point. Unrevealed strains may exist (as a correspondent points out this week) in war-worn vehicles, so that there would be a sporting risk in owning one.

An index to the advertisements in this issue will be found on the page facing the back cover.

The Tanner Force-feed Oil Pump.

An Automatic Pump Governed by Engine Speed and Throttle.

EVIDENCE is accumulating of the increasing interest taken, not only by designers but by motor cyclists in general, in a more scientific method of supplying oil to an engine. Therefore the subjoined description of a new device sent to us by the inventor, Mr. R. L. Tanner, of Lynmouth, Earlsdon Avenue, Coventry, is more than usually interesting.

In designing this pump the three principal objects aimed at were: (1.) To provide a pump that would automatically deliver oil to an engine in direct proportion to the engine speed and the throttle opening. (2.) To eliminate ball and other valves likely to give trouble, and substitute ports cut in the pump barrel and housing. (3.) To run the pump slowly enough to work satisfactorily at maximum engine speed. These objects are attained as follows:

A spring-actuated plunger A is attached to a finger B, which is raised by a spiral face cam C, rotated by the engine, and this finger is engaged by a stop D connected to the throttle by means of a Bowden cable E, so that the plunger stroke varies with the throttle opening.

The spiral face cam is formed at the side of a ratchet wheel F, actuated by a pawl G, oscillated by an eccentric H, attached to the magneto or timing gear spindle.

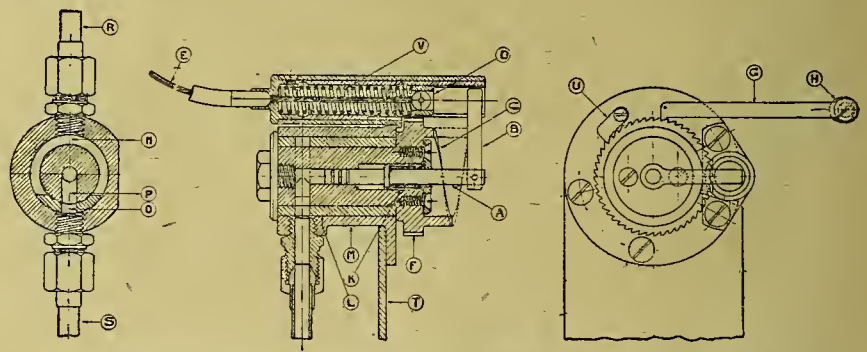
The plunger passes through the centre of the ratchet wheel, on the upper face of which is formed the spiral face cam, and upon the edge of this bears the finger of the plunger. The finger is pressed down on to the cam by a spring K, and the ratchet wheel is rotated by means of the pawl lifting the finger attached to the plunger, and then allowing it to drop rapidly under the action of its spring. The delivery is therefore forcible even when the engine is running slowly, and, owing to the gear reduction (approximately 100 to 1) obtained by the ratchet and pawl mechanism, the pump operates very slowly.

When the throttle is fully open the finger does not engage the stop, and therefore the plunger makes a full stroke. When the throttle is half closed the stop arrests the finger about half way on its delivery stroke and so on.

The barrel of the pump is formed integral with the ratchet wheel and spiral face cam, and revolves in the sleeve L, which is fixed in the housing M. In the sleeve is the suction inlet slot N and the outlet port O, and in the barrel the port P. As the barrel rotates, this latter port serves as a valve, putting the interior of the barrel into communication with the inlet R on the suction stroke of the pump plunger, and with the delivery outlet S on the return stroke. Thus the suction and the delivery are positively controlled, no automatic valves, which are liable to stick, being used.

The housing is attached to the crank case of the engine by the plate T, and two light springs (not shown in the drawing) are attached to the housing, one to the pawl G and the other to the check pawl U, the object of which is to keep these pawls in contact with the ratchet wheel.

The stop has a spring V behind it, which is sufficiently powerful, at all positions of the throttle, to resist the kick of the finger occasioned by the plunger spring.



The Tanner automatic force-feed oil pump, which raises the supply of the oil in accordance with the engine speed and throttle opening.

For convenience of drawing, the spiral face cam, finger, stop, and stop control, in the plan view, are turned through an angle of 90°, and the inlet union is omitted. The section clearly shows the relative positions of inlet and delivery unions, pump barrel, housing, and sleeve at the instant of delivery. In the plan view the position of the plunger is shown as it would appear the instant before delivery, and the stop in the position of full throttle.

The drawings depict the experimental model of the pump, but as a standard fitment it would be enclosed in the timing cover, and would be modified in several particulars.

FUTURE PETROL ALLOWANCES.

IT has been suggested that petrol allowances will ere long be further increased, but the latest announcement would suggest that this is too optimistic a view. The Petrol Committee has decided that all full duty petrol licences for motor cycle owners shall expire on March 31st. Motor cycle licences taken out this month are available for three months only; if taken in February for two months; in March for one month. The licences, originally issued for the autumn months of last year, on which some petrol remains to be purchased are still in force, and if a renewal application is made on the form on the old licence and accompanied by a five months licence fee, then a licence will be issued for the whole period.

There is no prospect of an increased allotment of fuel, though nothing definite has been decided in this direction. It is considered far more probable that the authorities will reduce the allowance.

BY IXION

Cooling the Plug.

A BIRMINGHAM reader recommends the notion of fastening a coiled spring round the base of a sparking plug which tends to overheat. The sole objection to this dodge is that the spring will have to be removed whenever the plug is taken out for any purpose, and if the spring is big enough to afford much extra cooling, it will take some wiring into position. Still, the idea is sound, and is specially suited for engines which will not take the dished cooling washers (such as the Fletcher) because there is no room to put a tube spanner on the plug. The reader in question is very pleased with the Polkey plug, a make unknown to me.

Hard Lines!

A "GENTLEMAN ranker," to use the old term, got a brief leave after a year in France, and on reaching home flew to the rather damp barn where his carefully greased single-cylinder was waiting. Nothing would induce the engine to start. An expert was called in, and soon spotted a stuck-up bell crank in the magneto contact breaker. Expert departs. Owner makes fresh efforts to start. No compression. After several hours' work it is discovered that the top piston ring is glued into its groove with carbon. Two days of an all too short leave wasted in tinkering. Amongst all our war philanthropies, we have forgotten to start a society for keeping khaki-owned motor cycles in tune against their owners' return.

A Striking Omission.

EVER since "Road Rider" started a discussion about the comparative merits of flat twins and single-cylinders, I have been waiting for some enthusiast on the big V twin to butt in; but so far I have been disappointed. After all, there are a great many men who ride the 7-9 h.p. type of machine solo, and I should have thought some of them would have been irritated by the partialities we have all been expressing for other types, especially as such preferences are really matters of individual taste, and "Road Rider" and myself have merely dared a prophecy as to which taste is likely to gain the ascendant. I have not been riding the 1,000 c.c. type of twin for several years past. My last experiments—now some years old—were not encouraging. Moreover, I dislike the weight of the big fellows; and, as I hardly ever use a sidecar, 500 c.c. usually does me pretty well. But my last long spin on a big V—a 6 h.p. Ariel—set me thinking; I thought it a pleasanter solo mount than the single-cylinder, and, if the flat twin had not proved all I expected, I had the big V twins in my mind's eye as a *pis aller*. They had not quite the perfect balance which I miss in the singles, but when you run them throttled well down on a high gear, they are charming—almost as smooth as a flat twin, and no fuss, whilst they naturally show more power, speed and acceleration than a single. Is it inevitable that the single-cylinder (failing the flat twin) should be the speedman's mount for all time? Is there any reason why some maker should not presently produce a light T.T. 5-6 h.p. twin? And if such a machine comes along, how would the single fare against it?

The Merits of the Single.

THE merits of the single-cylinder are, of course, obvious. It is at once the lightest and the simplest machine of any real power, and it affords quite as much comfort as the younger generation wants. You can decarbonise it, without scamping any detail, in an hour; and if you are a duffer, you can diagnose any petty trouble in minimum time. Simplicity is, however, a relative term, and for our purposes it means nothing more or less than the amount of trouble one must expect, and the time taken in diagnosis and repairs. On this score the single is, as yet, *facile princeps*, but the twins and the fours are fast overhauling it; before many years are past the twins will be no more troublesome or inaccessible than the single. About weight it is difficult to speak, when few catalogues are outspoken; but I imagine the single is still the lightest machine of its class, though I don't see why it should remain so. All I have written on this controversy may be tersely summed up; the "single" is the simplest and lightest machine of its power, but not the best balanced. When it has to meet competition from better balanced machines of approximately the same weight and simplicity, will it survive?

Lloyd George's One Blunder!

ONE of the most law-defying riders of my acquaintance lives in the country, and is medically unfit for military service. The local constable has been called up, and as the neighbourhood is tolerably free from serious crime, the authorities have appointed the lurid motor cyclist in question special constable for the district. Naturally, his first official act has been to abolish (silently and informally) the speed limit for that locality.

A Novel Rear Lamp.

WHEN I was examining the gadgets fitted by an enthusiastic 3 h.p. Enfield owner the other day, my eye fell on his tail lamp. He had got hold of a clip, consisting of two parallel C bands, and fastened it to his carrier. The space between the clip bands was filled with plasticine, in which were embedded a ruby glass and a small electric bulb. He claims it is the only vibration-proof tail lamp in Great Britain.

A Sixty Mile Trip along the Most Southerly Coast of Europe.

FOR many months I had been stationed at Gibraltar, and had rarely seen a motor cycle during that period, the exceptions being two or three 7-9 h.p. Indians, a 3½ h.p. Rudge Multi, and a couple of Douglases. No motor cycles from Spain appear to penetrate so far as Gibraltar, though there are a fair number of cars to be seen—especially sporting models of the Hispano-Suiza.

Imagine, then, my joy as a motor cycle enthusiast on seeing a brand new 1916 6 h.p. A.J.S. and sidecar buzzing merrily along an open stretch of road at a good 30 m.p.h. I soon found that this new importation belonged to Mr. Drew, of the E.T.C. cable ship *Amber*, and the latter gentleman lost no time in suggesting a trip to Tarifa, the most southern point in Europe, so that I might judge the paces of the A.J.S. for myself.

The A.J.S. outfit on which the journey was made.

We started early, as we wished to do a little exploring on foot, and had to be back by evening gunfire, but I soon had a taste of the speed of the A.J.S. On arriving at the Spanish Customs House in Linea, the smiling official, nodding a friendly recognition to my host, glanced at the pass and waved us through.

From here we had to make our way right round the bay to Algeciras, which lies directly opposite Gibraltar, and is connected by a service of steamers. Until a few months ago the new road to Linea had not been completed, and motorists had to leave their cars in Spain or have them hauled along the beach by mule and donkey power. Now, however, the road is roughly laid, and only waiting for the rains to set it. In England we would think it an execrable stretch of cobbles and pot-holes, but we were only too thankful for it here.

The historic town of Tarifa, showing the old fortress on the right

I, as the passenger, can vouch for the extraordinary comfort of the A.J.S. sidecar over this stretch, which we traversed at about 25 m.p.h., passing Campamento with its racecourse and polo ground, and striking a long, winding stretch of country lane inches deep in heavy white dust.

We crossed First River and Second River by elaborate iron girder bridges, and ran through two exceedingly picturesque fir tree plantations, and past quaint little roadside inns built of wood and thatch, one of which had an outside shelter covered by a thatch extended from four fir trees. We passed some Spanish infantrymen busy with a machine gun course, and, proceeding through the outskirts of Algeciras, we turned sharply to the right, where we struck the Cadiz road—a military road of wonderful engineering ingenuity and excellent surface. This road is excellently graded, and in places it winds for miles with a mountain on one side and a precipice on the other; at other points one can see it only for a few yards ahead as it winds its tortuous course between boulder and precipice. At one place the road drops very suddenly for several hundred feet, then follows a complicated S bend between two rocks. This danger point is indicated by one of the excellent Spanish road signs—a conspicuous white S on a black background.

To Tarifa.

After a steady climb of several miles from Algeciras the sea comes in view once more—a magnificent sight from this altitude, which makes the horizon appear so high that what one imagines to be sky is really sea, with the coast of Morocco across the Straits and Tangier at the water's edge. Soon after this the long descent to Tarifa begins, the little white town coming into view very suddenly between two cliffs.

Just before reaching Tarifa we stopped to take a photograph of the cemetery. The honeycomb in the far wall, which can be seen in the photograph, is used for the storage of coffins, and here they are allowed to remain as long as an annual payment is kept up. The moment these payments cease, however, the coffins are ejected and thrown on to the common heap—rather a brutal custom.

In addition to being famous as the most southern point in Europe, Tarifa is interesting for the part

In Spain with a Sidecar.—

it played in the fighting between the Moors and Spaniards, and its fortress is a magnificent old building.

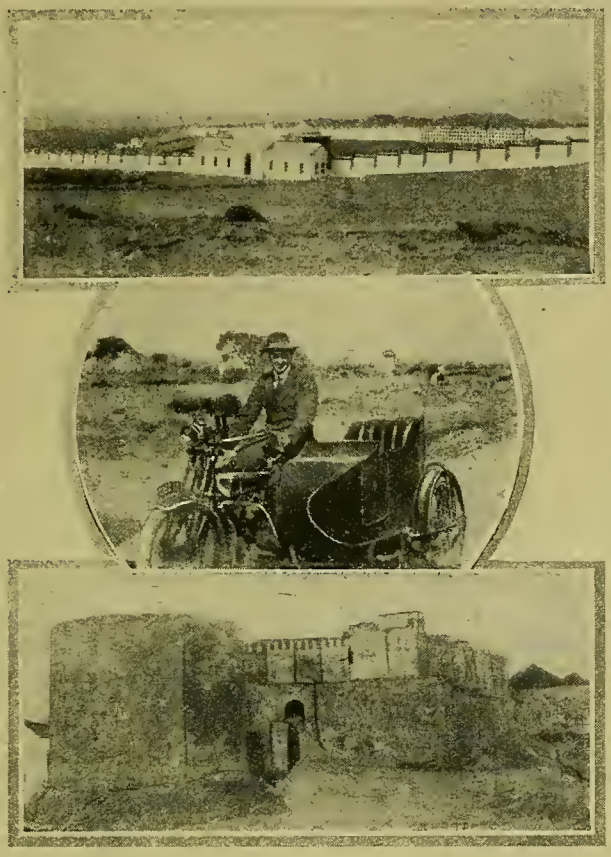
The town itself is a pretty little place. where dark fir trees show to advantage the quaint white buildings, and the mountains form an effective background.

Civility and Good Food.

The hotel is a crude place as compared with any English inn, but we were treated with great civility, and brought course after course of Spanish dishes, all well cooked and cleanly served.

After lunch we strolled round the town, and were pursued by a horde of children clamouring for "pennies"—the only English word they seem to know.

After a lounge and a smoke we returned to the outfit, and, starting up the engine at the first kick, were soon burbling up the hill out of the town on second gear. The wind that met us as we climbed the hill was terrific. This pass in the mountains is an outlet for gales blowing from the north or north-east, and has been known to blow the heavy A.J.S. outfit to a standstill—even when coasting downhill. To drive hard against such a gale is unsafe, especially downhill, as a sudden lull causes a most disconcerting acceleration which might prove disastrous on a bend.



(Top) The burying ground at Tarifa. For a yearly payment the coffin is left in one of the honeycomb partitions seen in the background, but if the payment is neglected the coffins is thrown on to a common heap.

(Centre) The A.J.S. sidecar in open country.

(Bottom) The old Moorish fortress at Tarifa, the scene of many historic and dramatic incidents in Moorish and Spanish history.

It was not long before we reached the crest of the ridge of mountains above Algeciras and were dropping down the long winding road that brings one back to something nearer sea level. Afterwards we made short work of the villainous road from Algeciras round the bay to Linea. After the atrocious surfaces of the roads that wind among the hills in a most tortuous fashion we found the fast going of the plains much to our satisfaction; and we let the engine have full throttle on the few straight stretches we encountered.

On the homeward journey, with the setting sun behind us, the hills and valleys looked their very best, and my only regret was that I had used all the films I brought with me.

Behaviour of the Natives.

Now a word about the behaviour of the people one meets on the road. It is well known that at Linea children run in front of horsemen and horsewomen galloping along the beach to polo or hunting and claim damages if knocked down, and the military are very quick to put any foreigner into prison if an accident occurs.

A Spanish A.C. road sign indicating a descent with hairpin bends.

In the country everyone gets out of the way quickly enough—whether out of politeness or fear I cannot say. Horsemen jumped the gulley at the roadside in order to give us the road in several cases, and the men in charge of the long trains of pack mules and donkeys were most anxious to get the animals on to the extreme edge of the road. As the average Spanish car is driven all out most of its time, this may have something to do with it, but the country people almost always gave us a wave of the hand and shouted "Adios" as we passed. They seemed extremely courteous — a great contrast to the townspeople.

The Iniquitous Mule.

Dogs, too, have a very bad name, but here again their bark seems worse than their bite, and though they look a very fierce tribe, they caused us no trouble beyond running alongside.

The only other animals to show signs of unfriendliness were a young bullock, which lowered its enormous horns, and a mule, which turned away with a characteristic anxiety to present its heels to anything dangerous, and threatened to put a hind leg through the sidecar wheel.

There are many old remains of historical buildings scattered about Southern Spain, most of which are associated with that turbulent period when the Moors and Spaniards were frequently in conflict. Antiquarians will find these districts prolific with objects of interest. The country is steeped in romance; but ever at its side stalks poverty, yet never that poverty that one might term wretched. The nature of the people prevents one getting that impression. Even the poorest of the poor seem to have philosophy which leads to a contentment with their lot that some people might envy, but many despise.

Altogether it was an enjoyable run, and if people choose the best roads—which they can have almost entirely to themselves—Spain is a most attractive country for a tour.

R.F.M.

THE POST-WAR MOTOR CYCLE.

A Few Notes on the Requirements of the Private Rider and on the Various Types of Engines likely to be used in the Future Motor Cycle.

By ERIC WILLIAMS, Holder of the Junior T.T.

Within a few months after winning the Junior T.T. of 1914, Eric Williams, late corporal R.E., was despatch riding in France. For many months he has been an inmate at a military hospital, where he has found time to study the weaknesses of motor cycles of the past which should be eliminated in the machine of the future. Mr. Williams refers to many interesting points anent singles, twins, and four-cylinder engines, gear boxes and spring frames, and suggests several improvements to the "flat twin" to make it the post-war ideal.

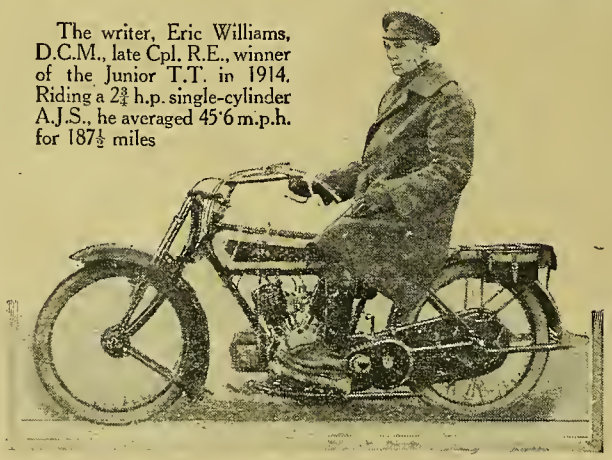
JUST now, when the reports from the various war fronts encourage one to think of an early victory, our thoughts naturally turn to the question of the post-war motor cycle. We wonder what the motor cycle manufacturers intend to offer the riding public. Have they yet made up their minds? Have they an ideal developed in the long interval since they last manufactured motor cycles? If so, will that ideal embody the ideas of the rider?

These questions probably are in the minds of most motor cyclists, whether they are in khaki or wearing a badge, and, no doubt, these riders and ex-riders of machines now two years behind their time have ideals also. Since the interests of riders and manufacturers are identical, let us consider the requirements of the average private owner, for a machine to meet these requirements must have the biggest sale in the boom which I am convinced will follow the cessation of hostilities.

We will take reliability for granted, as all first-class modern motor cycles can be called reliable. One would not ask the owner of a Rolls-Royce whether his car was reliable, neither need we consider this point in connection with any "class" motor cycle, as the trials have proved.

We require something more than reliability—something better than a machine which can be depended upon to take us to our destination, wherever that may be, and back again.

Let us take the popular 500-550 c.c. solo-sidecar machine: what are the requirements of the owner of such a machine? He wants absence of vibration, smoothness of running, accessibility (which makes for simplicity), and economy in petrol, oil, tyres, and transmission. How do existing singles of to-day compare on these points? Is such a machine our ideal? I think not. Its accessibility and simplicity are all that can be said in its favour, but on the strength of these points it will always have a fair sale with the man who has never tried anything better, the "knut" (not necessarily the speed merchant), and the amateur. The drawbacks of the single include its harshness when driving at low speeds on top gear, which does not enhance the life of belts, chains, and tyres. Makers sometimes overcome this fault by fitting a hand-operated clutch, which system unfairly uses the clutch until it will not stand up to the continual strain of slipping, and sometimes gets a permanent slip. On the point of vibration there are few singles I have ridden which do not have a "bad period" somewhere about 35 m.p.h., which fact is another point against the type when we are looking for our ideal.



The writer, Eric Williams, D.C.M., late Cpl. R.E., winner of the Junior T.T. in 1914. Riding a 2¾ h.p. single-cylinder A.J.S., he averaged 45·6 m.p.h. for 187½ miles

V Twin Advantages.

In the V twin engine we have a type possessing many advantages over the single. Its balance is not quite perfect, neither has it an even torque, so it cannot be described as the perfect power unit. I once considered the V engine perfection, and I am still in favour of it for many reasons.

The fact that it is a little out of balance and its slightly uneven torque are scarcely noticeable to the ordinary rider, and against these almost trivial disadvantages we can put down the important points that one may remove the cylinders with very little trouble. There are exceptions in the cases of some of the larger sizes, and among these the defaulters are chiefly American machines where it is often necessary to remove the complete power unit in order to get at the carbon. This operation would have to be done about every four months, more or less, if the engine were to be kept in perfect tune. This is truly a terrible state of affairs, but happily not found in the majority of the best British designs. In my opinion, there is no doubt that once a rider has experienced the delights of the twin, he will never go back to the single.

The Post-war Motor Cycle.—

But cannot we improve upon the V twin?

The flat twin is the answer. It is certainly an improvement upon both the single and the V types, because with it we obtain almost perfect balance and even torque. The life of tyres and transmission is remarkable compared with the single. Unfortunately these advantages are not unattended by disadvantages. On this latter point I have to admit I have yet to find the horizontal twin which is really accessible. With most engines of this type the complete power unit has to be removed for decarbonising, while even small adjustments are difficult.

With one engine of this type I recall being compelled to take the magneto to pieces in order to remove it for repairs.

If some engine designers will solve the accessibility problem, the flat twin will be the ideal power unit, as with the ideal engine it must be possible to slip off the cylinders, remove the carbon, grind in the valves, and reassemble in a couple of hours, in which time I have done this work on my single at the Front.

The above-mentioned disadvantages of the horizontal twin of to-day, to my mind, outweigh the advantages, and until the former are eliminated I prefer the old V twin. This represents the last word in accessibility, and is simple. With the advantages of these points in mind I can forgive its dot and carry one firing. Nevertheless it will not do for us to make shift with the "next best thing" because in the mechanically ideal type there are disadvantages which can be eliminated. The type has so many good points that the greatest efforts to overcome its few, but important, drawbacks will be more than justified. Its outside flywheel is a great point in its favour. We all know how that extra pumpful of oil when in doubt, as recommended by the makers, gums up the internal flywheels of the single and V types. This is obviated when the flywheel is outside. Then there is much in favour of the magneto position on the top of the crank case, where it is high and dry and in the very place where accessibility could best be obtained.

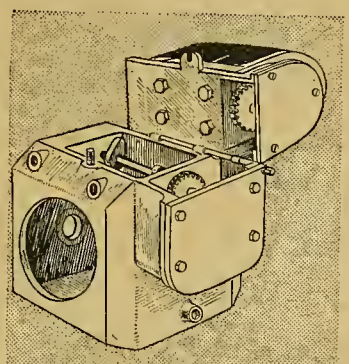
Why not have detachable heads? Copper and asbestos gaskets have supplanted the old method of boiled oil for securing a gas-tight joint. In the car world this feature is rapidly coming to the front, and there can be nothing against its adoption in the motor cycle. The head could be secured by a cross-piece, and very little clearance between the head and the frame would be necessary. Such a detachable head could be slipped off in a few minutes and cleaned out perfectly and valves ground in with the greatest ease.

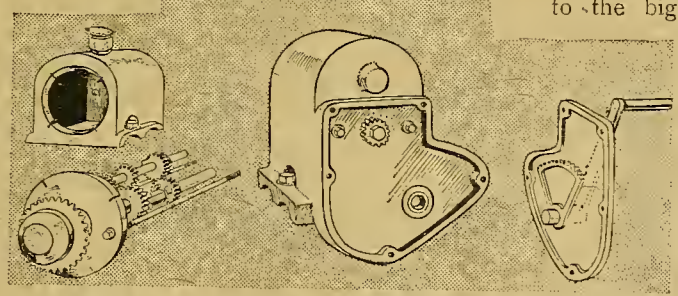
The magneto must be more accessible. At present it is hemmed in by the flywheel on one side and the timing case on the other, while over it is the cross tube of the frame. It is particularly desirable that the design should allow the removal of the contact breaker without disturbing the flywheel.

The connections between cylinders and induction pipes should be such that they may be readily attached and detached and gastight joints easily and quickly made. The induction pipes should also have a hot-air jacket with a Claudel automatic carburetter centrally fitted under the pipe and out of the way of one's legs. The machine should be tuned to give a tick over in free engine and low speeds and capable of violent acceleration.

A FEW SUGGESTIONS AND DESIGNS INTENDED TO OBVIATE THE FAULTS MENTIONED IN THIS ARTICLE.

A suggestion of our technical staff to render accessible the magneto on a flat twin. The magneto base is hinged on the cover of the crank case, and when swung over as indicated the contact breaker is clear of the flywheel.





A simple form of gear box in one piece, with cover carrying the bearings on one side. The cover has a slightly coned edge, and is drawn into position by means of two long bolts, which pass through the gear box and the blank end of the casting. By means of this design it is suggested that the whole of the gears could be drawn out of the box by removing two nuts.

The simple gear box here illustrated is fitted with kick starter To remove the gears in this case the kick starter cover would first be detached, when by taking off the starting pinion the *modus operand* would be as already described.

Forced Feed Lubrication.

The lubrication of the post-war motor cycle should be by means of a small mechanical pump, which would force oil through a drilled crankshaft to the big ends, at the same time keeping a constant level in the crank case.

The Gear Box.

We have many examples of three-speed gear boxes fitted with clutch and kick starter, but many of these are huge and cumbersome, not only on the point of appearance; also they are difficult to take down, adjust, or clean. Strong and reliable they may be, but we have progressed a little beyond this, and, in addition to efficiency, we must have neatness in design and, what is more important, accessibility. We must have some means of getting at the gears without being compelled to take the complete gear box to pieces.

Other items in the specification of the post-war ideal would include a hand-operated cork clutch with a spring easily adjustable. The transmission would be by chains throughout, and *properly enclosed in cases with inspection doors*. The brakes would be of the internal expanding type, embodied in the rear driving sprocket, and operated by hand and foot. The wheels should be detachable and interchangeable, and

The Post-war Motor Cycle.—

of a design which would permit a change over to be made in a couple of minutes, the transmission, brakes, and controls remaining undisturbed. The frame should consist only of straight tubes with a duplex tank, and the steering head should be long and substantial in construction.

The Spring Frame.

Although *The Motor Cycle* spring frame campaign went very strongly for a time, the results appear to be discouraging, but I realise that many designs may not yet be made public. Of the designs published, very few were really practicable, but, of course, many were just the ideas of readers who lacked mechanical knowledge. In my opinion what is wanted is a machine sprung at the rear by cantilever springs, and a spring front fork which will have at least five or six inches movement.

The Four-cylinder.

The four-cylinder engine is the power unit for a sidecar mount. So far the development of this type of engine has been retarded by insufficient interest on the part of both rider and maker. Probably the older engines of small size fitted with automatic inlet valves have given the type a bad name, but it is to be hoped that experiments will be undertaken after the war is over. An engine with four cylinders should not be smaller than 1,000 c.c. capacity, *i.e.*, 250 c.c. per cylinder; such an engine would be ideal for sidecar work. The cylinders of the so-called 4-5 h.p. F.N.'s which had a.i. valves were altogether too small, being less than 125 c.c. capacity. We know that a light weight engine of this size is only a toy model, but engines like the J.A.P. 2½ h.p. have demonstrated what can be done with slightly larger cylinders.

I have not used a four-cylinder machine for any length of time, but what riding I have done on this type has left the impression that it has a great future. How noticeably the motor cycle has followed the car during the past few years! I am sure we cannot go far wrong in this, and in cars the four-cylinder engine is the recognised standard power unit.

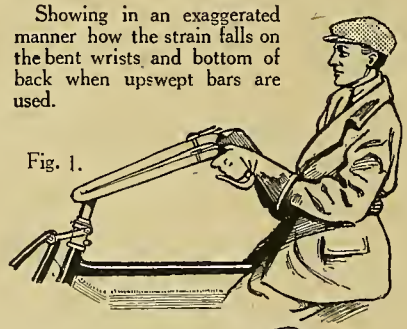
The four-cylinder engine lends itself to the car type gear box and shaft drive to the rear wheel, which should have worm drive. I will admit I have nothing very definite in my mind to account for my confidence in the four-cylinder engine as the prime mover in the future motor cycle, but it has a future as a sidecar mount, I am sure, and should not be neglected.

HANDLE-BAR DESIGN.

WHY THE SEMI-T.T. IS SUPERIOR TO THE UPTURNED BAR.

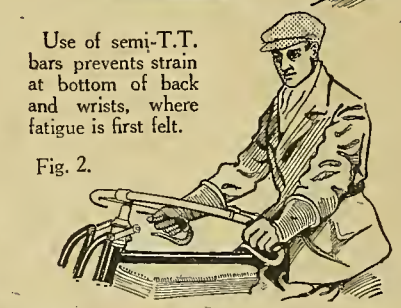
I THINK it is becoming generally realised that standard touring bars, like standard mudguards, fall short of practical requirements. Many an excellent machine, particularly among those of the heavy sidecar variety, is rendered uncomfortable and tiring to ride simply on account of its badly designed bars.

The rider of a motor cycle is subjected to a certain tiring strain which does not exist in the case of a pedal cycle, namely, that which is caused by the forward pull of the machine when accelerating and by wind resistance. The latter force is tending to push him backwards off the saddle, and the former to pull the machine from under him. Fig. 1 shows the position of the rider on a machine fitted with ordinary touring bars of the upturned variety.



Showing in an exaggerated manner how the strain falls on the bent wrists and bottom of back when upswept bars are used.

Fig. 1.



Use of semi-T.T. bars prevents strain at bottom of back and wrists, where fatigue is first felt.

Fig. 2.

It will be observed that the arms and wrists of the rider are bent, which imposes fatigue on the arm muscles. No doubt many riders are familiar with that dull aching about the wrists and elbows after a long ride, signifying that their riding position is strained and unnatural. Unless, when in an upright position, one holds tightly to the bars with arm muscles tense, the strain falls at the bottom of the back and in the joints of one's hips. Strain at these points very soon causes fatigue, and my last long trip (assuredly my last!) on a machine fitted with bars of the "high" variety left me with backache for a fortnight. The machine was a powerful twin, ridden solo, and I could have ridden my usual semi-T.T. solo mount for double the distance without experiencing similar fatigue.

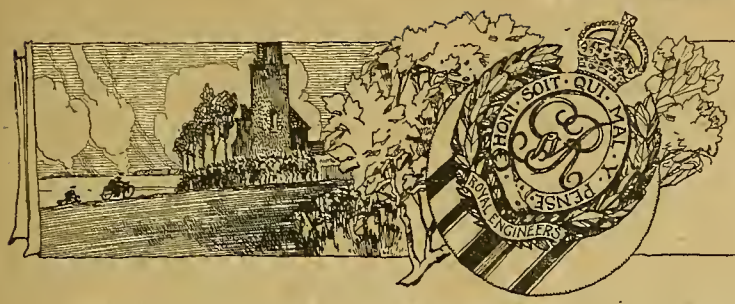
The Better Pattern.

Fig. 2 shows the type of bar which, in the writer's opinion, is by far the most comfortable and natural—quite apart from perfection of control. I do not advocate T.T. bars for the ordinary potterer, and dropped bars are out of place except on the track. The semi-T.T. bar, on the other hand, is not ugly, and is by far the best engineering compromise yet arrived at.

Referring to fig. 2, it will be observed that the arms and wrists of the rider are straight, and no strain is thrown upon the arm and wrist muscles, while the body of the rider is inclined very slightly forward, this assisting still further in easing the arms, while it removes all strain from that vulnerable point—the bottom of the back, at which fatigue begins.

Much has been learnt as regards riding position, and in all probability the war will see the last of raised handle-bars, which demand an additional fitment, viz., a back rest, when applied to a motor cycle.

H.M.B.



MILITARY NOTES.

"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS „TANKS."

ARMOURED SIDECAR OUTFITS.

AMERICAN machine gun outfits may yet be heard of in the Russian and French war zones. We are informed by the Signet Rear Car Co., of Buffalo, N.Y., that their machine gun carriage recently passed the final test by the Russian and French Commissioners, and has been approved for field use, but this does not necessarily mean that orders have been placed.

GALLANTRY WITH THE "TANKS."

THE Military Cross has been awarded to Lt. F. A. (Eric) Robinson, of Seven Kings, for great gallantry displayed whilst in command of a "Tank." After tremendous fighting his machine became "ditched," which necessitated fourteen hours' hard digging under heavy fire to release it. On another occasion his "Tank" was hit by a direct shell and damaged, but he got his men out safely and immediately went into the trenches and worked a machine gun.

Lieut. Robinson joined the Navy in November of 1914, entering the R.N.A.S., later transferring to the M.G.C., in which he obtained a commission. He is a keen motor cyclist, his mount being a Zenith.

CPL. A. J. SPROSTON'S VIEWS OF INDIA.

IN a chatty and interesting letter to Mr. Alec S. Ross, which we were courteously permitted to peruse, Cpl. A. J. Sproston, who has had experience in France, Egypt, and Mesopotamia, and is now stationed at Poona, India, speaks enthusiastically of the future possibilities of the motor cycle in India. Cpl. Sproston writes:

"The commercial possibilities of this great country are unending. With the rapid strides in education, an elaborate and efficient railway system, a network of roads in excellent condition, rivalling our own at home, it requires only a superficial survey to enable one to decide that any home manufacturer establishing his products here would be amply repaid for his enterprise. It is a sad fact," Cpl. Sproston continues, "that our cousins of the 'nasal note' have long realised that this country is excellently served by the press, almost every district having a daily journal of some sort, and in the cities and villages hoardings bearing picturesque illustrations complete an advertising campaign that is such a prominent feature of the periodicals referred to. So we find the American car predominant, though the trade here tell me that their clients would take English machines if they could get them. I was talking with a dealer the other day, who dilated on the preference of his customers (both black and white) for the English-made machine, but his tribulations on the score of delivery would have melted the heart of a Jew."

Cpl. Sproston left France in June, 1915, and in August that year went to Egypt. January, 1916, found him *en route* for Mesopotamia, where his experiences were not exactly rosy, and in July, 1916, he was invalided to India.

Lt. F. A. (Eric) Robinson, to whom the Military Cross has been awarded for great gallantry whilst in command of a "Tank." His wife is proudly wearing the coveted honour. They are both keen sidecarists, the motor cycle being on this occasion a Bradbury, though the Zenith was most frequently Lt. Robinson's mount in peace time.

T.T. RIDER IN HOSPITAL.

WE regret to hear that Capt. Noel E. Drury, Royal Dublin Fusiliers, who will be recalled as a frequent competitor in T.T. races of the past, is at present in hospital at Manchester, having been invalided home from Salonica. Fortunately, his injury is not regarded as likely to prove of permanent character, and he hopes soon to be on sick leave.

FLAT TWINS.

L.-CPL. GEORGE HOGG sends the following letter, written in the desert of Sinai. The flat twin controversy, judging from our correspondence, has created nearly as much interest Overseas as it has done at home:

"I have often intended to let you know how much I appreciate your paper out here. I did not read it before the war, but after I enlisted, nearly two years ago, I commenced to get it weekly. Since I came out here nearly six months ago, I have received it regularly, and always enjoy it. There are no motor cycles where we are, but at the bases they are plentiful. Douglases and Triumphs being in the majority. I enjoyed your article on 'flat twins' in your issue of November 9th, and, although not an expert, I think they are as near the ideal engine as one could wish. Every success!

"GEORGE HOGG (L.-Cpl.)."

Cpl. H. J. Mansfield, Heavy Section Machine Gun Corps. He is now participating in the "great adventure," and the last we heard was that he was with the "Tanks" on the Somme. He is, by the way, a recruit of *The Motor Cycle*, and an Indian enthusiast.

IN VERDUN'S "BACKGROUND."

VERDUN—what a mighty word, and how tremendously significant! The utterance of the two syllables stirs the imagination as but few words do.

ACTUAL PHOTOGRAPHS FROM THE "BACK OF THE FRONT!"

One can picture those stupendous attacks and repulses on the blood-stained slopes of Douaumont more vividly than any other phase of the conflict on the Western front or any other front, and it will be of interest to know that the photographs we reproduce were taken in the vicinity of this battlefield by a French officer who has many times contributed to *The Motor Cycle*. In his own phraseology he describes the conditions thus:

"These are photographs from Verdun's background on the occasion of another visit. I can state that the conditions of work for the despatch riders at Verdun and the neighbourhood are harder than anywhere else on the French front. They are indescribable. I can say that the chief annoyances are mud, material fallen on the ground, and drivers of horses charging one in the darkness of the night."

WELL-KNOWN MOTOR CYCLISTS HONOURED.

BOTH the well known exponents of A.J.S. machines, Cpl. Cyril Williams and Eric Williams (late Cpl.), who are, by the way, unrelated, have received honours for bravery in the field. The latter, it will be recalled, received the D.C.M. many months ago, and the latest news is that Cpl. Cyril Williams has been awarded the Military Medal. Congratulations!

New readers may be reminded that Eric was first and Cyril second in the Junior T.T. Race of 1914.

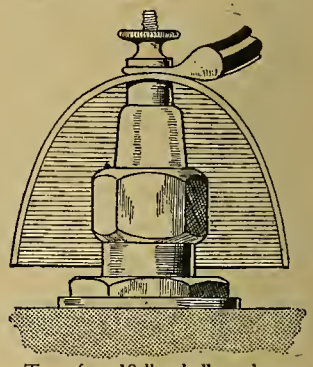
We learn also that Neville Hall, the O.K. rider who performed conspicuously in the 1914 Six Days Trial, is one of the latest recipients of the Military Medal.

PRACTICAL USE OF WAR SOUVENIRS.

A FRENCH officer attached to the British forces in the field makes use, as a plug protector, of the following original device:

His machine is a Douglas, and he has done much riding at the Front under the very worst weather conditions. He found that when he rode through a heavy fall of rain the engine stopped as often as every 300 yards or so, the plugs being coated with thick yellow mud, and thus short-circuited. Binding them with black adhesive tape cured this, but caused a tendency to overheat.

He then made use of two shell caps (eighteen-pounders, brass protectors) picked up on the battlefield. He had a hole drilled through the top, the circular



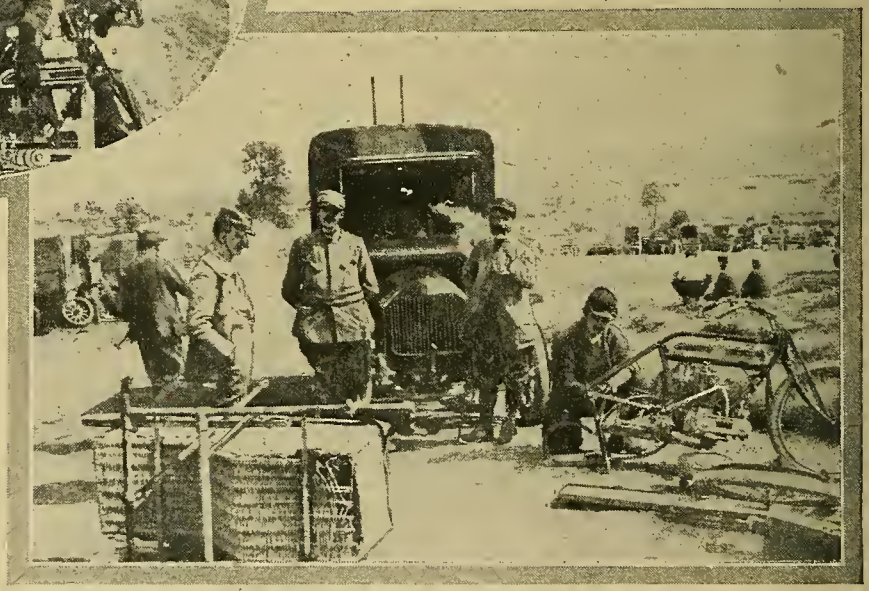
Top of an 18 lb. shell used as a plug protector

base being cut shorter so as to clear the cylinder, and simply fixed one on to each plug, the result being a very good protection against oil, water, and mud.

The two polished brass bells give a distinctive appearance to the engine, and another advantage was gained by fitting them. They constitute, by their large radiating surface, a most efficient and useful plug-cooling device—surely the most war-like and, perhaps, the simplest now in use.

THE "TANKS" IN ACTION.

SINCE motor cyclists and motorists recruited through *The Motor Cycle* play so prominent a part in the successful operation of the now famous armoured car "Tanks," there is bound to be a general flocking of our readers to the various picture theatres at which the Tank film is to be shown. The films were released for exhibition in the London district this week, and will be shown throughout the provinces.



British motor cycles are in evidence on all the Allied fronts—French, Russian, Italian, and Serbian. The pictures show a W.D. Triumph at the "back" of Verdun. The mechanic has detached the wicker sidecar (a type of double-purpose carrier in extensive use on the French front) to assist in tyre-mending operations on his machine.

A *GOOD* trade mark will suggest at a glance some attractive thought about the goods it sponsors—their uses or qualities.

¶ That is why the Stonehenge Trilithon was chosen as the trade mark of Avon Tyres—primarily because the manufacturers' ideal could be best expressed by a symbol connoting strength and endurance as the outstanding qualities of Avon Tyres. . . .

¶ Secondly, there is the important matter of origin. Stonehenge is essentially British, and "British tyres for British motorists" is no mere slogan of sentiment in these days. It voices a law of national preservation, and no true patriot will be satisfied with anything less than the genuine old English savour such as is created by the mark of the Avon Company—rubber manufacturers at Melksham in Wiltshire since 1885.

In answering this advertisement it is desirable to mention "The Motor Cycle." B5

It's a muddy road and a bloody road,
And a road that's swept by fire,
But we've got to get through with the Orders 'bus
Or we'll raise the C.O.'s ire.

So you'll hold at the bend, I know, old girl,
You'll stick it and turn not a hair,
Just one more dash! Through one more splash!
And we're there, old girl, we're there!

The Dunlop rubber-studded non-skid motor-cycle cover.

The British Motor Industry after the War.

Important Questions affecting the Preservation of the Motor Industry.

IN discussing the subject of foreign competition, and the desirability or otherwise of a protective tariff for the British motor industry, *The Autocar* (January 6th) sets forward a number of interesting figures which clearly indicate the position of the motor car industry to-day, and cause one seriously to reflect whether some protective measures will not be necessary if it is to enjoy a reasonable degree of Overseas trade. The figures show to how great an extent American trade has increased since competition ceased, so far as England and Europe are concerned, in 1914, but, though these figures are of interest to every motorist, it does not necessarily follow that the outlook of the motor cycle industry is equally depressing.

It is roughly estimated that 60% to 70% of the motor cycles used in British Overseas possessions to-day are of British manufacture, whereas the number of British-made motor cars used in the same countries is set down as low as 15%.

The figures given in our sister journal convey a good idea as to the general position of things, and they are of particular interest to motor cyclists, because the motor cycle industry is to-day in much the same position as the motor car industry, and both will require every possible support and encouragement in order to recover from the effects of the war.

The Growth of American Trade.

Even had there been no war, American competition would have become serious, and this fact *The Autocar* illustrates by giving the figures as to importation. In 1914 American motor car imports to England exceeded those of 1913 by £598,156—truly a substantial increase—and the fact that American manufacturers will find themselves in an infinitely stronger position after the war is shown by motor car sales in America alone—the number of cars sold in the States in 1916 exceeding the number sold there in 1914 by 1,195,665. For the year ended July, 1916, the Ford output was 533,921 vehicles, or rather more than double the total number of private cars in the British Isles!

These instructive figures convey some idea as to the immensity of the American motor car industry, and that the American motor cycle industry, with its extensive home market and rapidly expanding Overseas trade, may attain similar dimensions in a comparatively short space of time is well within the range of possibility.

Our Small Home Market.

The writer further points out that this huge American industry has been built up behind a 45% tariff, but even if this tariff were abolished it would have very little effect upon the British industry, because the American industry is so thoroughly established on such a huge basis.

Another point to be considered is that the American market is at the factory door, whereas the British Empire is spread over the whole world. Therefore the American manufacturer is in a position to obtain the full benefit of a home tariff, whereas a similar tariff here would, at the best, only secure for the British manufacturer the possession of our small home market, which is certainly insufficient for the prosperity of more than a few firms.

Existing Tariff Inadequate.

The 10% preferential tariff which has hitherto existed in most of our Dominions and Commonwealths has proved insufficient to prevent the Americans, aided by their system of "quantity production," from underselling British vehicles everywhere, which is shown by the fact that out of 200,000 cars owned by the British Overseas Empire, only 30,000 were British! If British machines are really to be established in British possessions throughout the world, the preferential tariff must at least be as beneficial to British manufacturers as the home tariff, and such an arrangement would give the British manufacturer a fair chance, which is more than he has enjoyed hitherto.

Probable Changes in Production Methods.

The Autocar points out that after the war certain changes in the system of production may occur, and the tendency before the war was for each individual firm to confine itself to one or two models only, instead of making a number of different types. Then, again, it is probable that the manufacture of machines from components, built by component specialists, will become general; but before any such system bears fruit we must assure ourselves of a wider market than the British Isles present.

British methods of distribution and selling Overseas have not compared favourably with American methods, and the British industry has suffered from lack of serious attempt to provide suitable machines for Overseas conditions.

What would be the Effects of a Tariff?

Our contemporary considers that, so far as it is possible to foresee the effects of a protective tariff, everything would depend upon the amount of the duty. A small duty would be of very little service for the reasons explained, but a high duty, say from 50% to a minimum of 33⅓%, would not only help the industry to recover from the effects of the war, but would also provide some certainty of tenure for the home market. The danger of home prices becoming inflated as a result, or of new trusts or similar combinations being formed, does not appear to have become conspicuous in other countries, which have long enjoyed the shelter of a protected market.

TIMES TO LIGHT LAMPS.

GREENWICH TIME.

Jan. 18	...	...	4.52 p.m.
,, 20	...	...	4.56 ,,
,, 22	...	...	4.58 ,,
,, 24	...	...	5.2 ,,

New Road Record Claimed.

News of a new road record in America is to hand. H. Parsons, on a Harley-Davidson, claims to be the first to have covered 200 miles in 200m. on an open road. His time for ten miles was 7m. 21s. = 81½ m.p.h.

Automobile Association's Reduced Fee.

A reduction in the entrance fee for membership of the Automobile Association has been conceded. Motor cyclists may join at once on payment of 13s. 6d., covering membership up to April 30th, 1918. Light car owners may join for £1 6s. 6d., and car owners for £2 12s. 6d. The advantage of this concession will no doubt be taken by many motorists.

Dunlop Rubber Co.'s Dividend.

The directors of the Dunlop Rubber Co., Ltd., report that the nett profit for the year, including the amount brought forward from last year, is £507,967. The 6% dividend on the preference shares has already been paid, also an interim dividend on the ordinary shares at the rate of 10% per annum for the six months to February 28th, 1916, and a second interim dividend at the rate of 20% per annum for the six months to August 31st, 1916.

Motor Cyclists and Light Cars.

Many readers of this journal are prospective owners of light cars, and those who are contemplating a four-wheeler will be specially interested this week in our sister journal *The Light Car* of Wednesday, 17th inst. The issue contains articles and illustrations descriptive of economical winter cars, and demonstrates the importance of selecting a body which will be a double-purpose one, *i.e.*, suitable for winter and summer use. Such a one is the coupé. Other features are an illustrated article entitled "A Coupé in the Making," which describes a visit to a coachbuilder's, and the whole process of body building. More attractive bodies of the permanently closed type are also dealt with, and the usual features are retained.

Fellows Magneto Co.

Preferred shares to the value of over £46,000, out of the 50,000 8% shares offered, have been subscribed for and allotted by the directors.

Parts for Foreign Machines.

The prohibition of foreign machines and parts is certainly beginning to have its effect in this country. A reader has been three months waiting for a cylinder for his American made motor cycle and has not yet been successful in obtaining one. As every novice knows, imports of motor parts are prohibited.

A Good Ship Lost.

It is always sad to hear of a good ship being sent to the bottom, and it is with great regret that we learned last week that H.M.S. *Ben-my-chree*, the seaplane carrier, was sunk by gunfire in Kastelorizo Harbour, Asia Minor. Commander C. R. Samson, R.N., D.S.O., the pioneer seaplane flier of the British Navy, was in command. Before the war *Ben-my-chree* was the crack ship of the Isle of Man Steam Packet Co.'s fleet, and carried many hundreds of motor cyclists and their machines to participate in or view the Tourist Trophy races. She was a triple screw turbine ship, capable of twenty-five knots, and was the largest of the flotilla. Several other I.O.M. ships have done, and are doing, splendid work in H.M. Navy.

A "Waterbury" Motor Cycle.

Mr. J. V. Watson, a well-known Southport motor cyclist, describes a curious and amusing experience which befell a local doctor who had borrowed an Elswick sidecar outfit for the period that his Belsize car was undergoing repairs. Not being accustomed to the three-wheeled vehicle, the doctor contrived in some way to run the machine into a ditch containing about four feet of muddy water, himself falling clear into a field of potatoes. The machine stood in the ditch, immersed to the handle-bars, for fully twenty minutes, but when finally hauled ashore the kick starter was given a few digs, and, to the surprise of all, the engine began to fire! It conveyed its rider a distance of seven miles, finally stopping within a few yards of his home—a most surprising and obliging performance.

Fines relative to Speed.

We see that the Chief of Police in Denver, U.S.A., suggests that in order to prevent the speed limit being exceeded fines should vary accordingly, and that $5, *i.e.*, £1 per mile per hour above the limit ought to be an effective method. Although at the above rate the fines would be extremely heavy, the idea certainly sounds a fair one, and would prove much fairer than some of the unequal fines sometimes imposed in this country. Who is to estimate the speed—the constable or the rider?

The V.A.D. and Red Cross Work.

The useful work of the 5th East Lancashire V.A.D., Manchester, is being augmented by the addition of a Motor Transport Section, comprising motor cars and combinations. The duties of the motor cyclists are, on receipt of telephonic instructions from headquarters, to form bearer parties to unload trains of wounded soldiers and convey the men to the various hospitals. As Manchester is said to be the largest distributing centre for wounded soldiers in the kingdom, there is generally plenty of work to be done which is entirely voluntary. Offers of help should be made to Sec.-Lt. Woods at Newbury Hospital, or at 287, Deansgate, Manchester.

Despatch riders attached to our gallant French Ally. Desvarenne (fourth from left) is well known in France as an exponent of the Morgan runabout.

Less Petrol Probable.

The suggestion of a possible reduction in petrol allowances after April will come as a shock to motorists.

The National War Funds.

At the week-end the principal war funds stood as follow :

The Prince of Wales's Fund (distributed £3,529,719)	£6,022,829	0	0
British Red Cross Fund	5,960,897	0	0
Tobacco Fund	123,751	0	0

A Strenuous Test.

During a recent visit to the works of Messrs. A. J. Stevens and Co., Ltd., we were able to examine several engines under load test on the bench. The engines are run on full load for eighteen hours without any concentrated air draught, the fuel used being coal gas from the town main. We are told that the engines seldom overheat during this strenuous test, though coal gas gives a very much hotter explosion than petrol.

Running on Coal Gas.

The A.J.S. testers state that coal gas is not very satisfactory as a fuel. The explosion it gives is more by way of being a detonation than that of petrol, and though an engine will "rev." indefinitely on coal gas, it gives off little power. An engine which will develop about 8 b.h.p. on petrol will seldom develop more than 4 b.h.p. on coal gas.

Measuring Gradients.

Is a gradient of 1 in 1 vertical? We have heard this point disputed many times, so perhaps a brief explanation will clear the atmosphere. In railway engineering a gradient of 1 in 1 is vertical, the distance being measured in this case along the surface traversed, but in road engineering a gradient of 1 in 1 is equivalent to 45°. In road engineering the measurements are made along the two sides of the triangle which adjoin the right angle.

The Newcastle Motor Club.

The Newcastle Motor Club held its annual general meeting on the 9th inst., and, judging from the report we have received, the club still seems to be in a fairly flourishing state. Last year funds were utilised in providing comforts for wounded soldiers in local hospitals, and we are informed that practically the whole of the club has qualified for first-aid work. Following upon this, the club is associated with the V.A.T.S. (Air Raids), and the members perform duty in calling the nurses to the various stations

Warning to Petrol Users.

The daily papers on Tuesday published a statement to the effect that the Petrol Control Committee had learned that motor spirit licensed for consumption, free of duty, in commercial vehicles, is in some cases being used in private cars without the full duty being paid, and also that motor spirit is being supplied by retailers without any corresponding entry on the licence. The committee gives notice that proceedings will be taken against offenders. As a matter of fact, as *The Motor Cycle* has pointed out before, the system of petrol distribution by licence is open to all sorts of tricks (some of which we have exposed) and possible evasions.

War Loan.

The Dunlop Rubber Co., Ltd., has applied for a quarter of a million of the new loan.

Values of Second-hand Machines.

The question as to the extent to which the present inflated prices of second-hand motor cycles will be affected when peace returns is discussed in our leader this week.

From Motor Cycle to Light Car.

Many motor cyclists know Miss Nora Hough by name as a pre-war competition rider on a Douglas. In Wednesday's issue of *The Light Car* she relates her experiences with a light car coupé, under the title of "Leaves from a Lady's Log Book."

The Trade and National Service.

The position of the motor cycle trade, as outlined in our leading article of January 4th, is still being discussed anxiously by leading men in the trade. It is hoped and expected that Mr. Neville Chamberlain, the Director General of National Service, will be sympathetic to an industry which has rendered such good service in the war and brought to this country so much gold.

A Rotary-engined Motor Cycle.

When *The City of Birmingham* went down some few weeks ago there was on board a most interesting new design of motor bicycle possessing a rotary engine. The machine is the invention of a native of India, and he was taking this forerunner of a model, which is intended to startle the earth, back to India with him. The inventor is very optimistic as to the success of his design, and is confident that it will not be long before public curiosity in the successful application of the rotary engine to a motor cycle is satisfied. Though the man responsible for the machine obtained particulars of insurance facilities, at the last moment he decided not to avail himself of them. Bad luck indeed! We learn that other specimens are well on the way.

A Motor Cycle Thief.

In our issue of December 14th we mentioned a case where a man in uniform wearing shoulder letters of the 7th Lancers (which regiment does not exist) had succeeded in stealing a motor cycle. Evidently the same person is at work again, for the Metropolitan Police are on the look out for a man about twenty-four years of age, wearing khaki, with two wound stripes on the left arm, who states that he is in the Lancers, and attempts to victimise persons with motor cycles for sale. Just lately, it is alleged, the man has succeeded in getting away with machines from Shepperton, Battersea, and Wandsworth. He always tells the same tale, that his commanding officer has seen the machine advertised in the papers and had sent him to try it with a view to purchase. To one of his victims, an Army officer, he produced a forged letter from a colonel in the Lancers, authorising him to try the cycle. The wanted man is about 5ft. 8in. in height, and has a very sallow complexion. He has two gold teeth in his upper jaw. He invariably replies to advertisements which have appeared in *The Motor Cycle*.

A Machine Gun Demonstration.

On Friday, the 12th inst., the Blackpool Motor Volunteers were given a demonstration of the latest Lewis machine gun, a sample of which was secured for the purpose by Cpl. T. Sharples. It was shown how deadly a weapon this gun may be in the hands of an experienced marksman, and it is hoped that the Corps will soon secure one of their own. These guns have a range of over 2,000 yards.

The Best Use of Men "Called Up."

In assuring the Government of its desire to assist the Director of National Service in any way possible, the Executive Council of the Association of Chambers of Commerce of the United Kingdom points ont that "from its own experience as representing many of the principal cities and towns in the United Kingdom the best use is not being made of the men now called up, in that more men than are necessary are being employed upon work; that men having definite duties have not enough work to fill up their time; and that men are often not placed in positions for which their previous experience qualifies them."

Another "Just So" Story.

A correspondent to the *Hull Daily Mail* gives a very entertaining account of a despatch rider's adventure in East Africa. He says :

"One of the squadron motor cyclists dashing along the road with a despatch became suddenly aware of a rhinoceros which bore down npon him, passing close behind him. An exciting chase ensued, which resulted in the cyclist abandoning the bicycle to its fate, and hiding himself in the long grass. In all probability the fumes from the petrol prevented the rhinoceros scenting the cyclist, for he spent some time in cautious examination of this new inhabitant of the jungle. Then he trotted off, and the motor cyclist attempted to regain possession of his machine.

"To his horror, however, he perceived the rhinoceros returning, and again fled to cover. However, the great beast, which showed signs of having been wounded, disappeared."

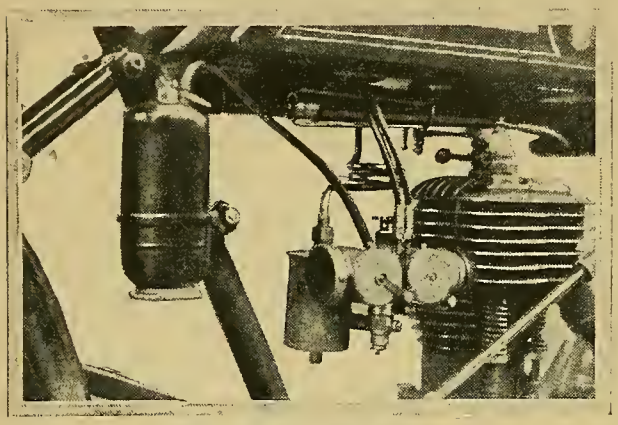
1917 American Models in England.

We have received a letter from the Wulfruna Engineering Co., Ltd., which asks pertinently how 1917 model Harley-Davidson motor cycles can be offered in face of the embargo on foreign imports of motor vehicles, and suggesting that the Motor Cycle Manufacturers' Union should take the matter up. The Wulfruna Co.'s representative is moved to complain by reason of the fact that the British Government is stopping the production of motor cycles in this country from the 15th proximo, as mentioned in our last issue. We are able to throw some light on this case. The facts, as we understand them, are that a few weeks ago, at short notice, the Harley-Davidson Co. agreed to release the whole of its stock of H.D. machines to the Russian Government for Army purposes on the condition that they were granted a permit by the Board of Trade to import new machines from America to replace the stock. This course, in the exceptional conditions, was allowed.

STARTING ON ACETYLENE.

A Convenient Method of Starting an Engine run on Heavy Fuel.

IT has been known for a long time that an engine can be run on acetylene gas. Acetylene gas, however, is somewhat uncertain in its action, and therefore it is not advisable to run an engine continuously on it. This gas has been employed successfully by Mr. H. G. Passey, model railway engineer, 74, Bertram Road, Hendon, London, N.W., for the purpose of starting his $4\frac{1}{4}$ h.p. B.S.A. motor bicycle when using pure paraffin. The jet consists of a $\frac{1}{8}$in. brass tube fixed into the vaporising chamber of the B.S.A. carburetter, having a $\frac{1}{16}$in. hole. To start the machine the paraffin is turned on, the carburetter flooded, and the water turned on in the small generator, which is connected to the auxiliary jet by means of a rubber tube. After injecting paraffin into the cylinder for the purpose of freeing the rings the engine may be started. The machine in question is a 1917 model $4\frac{1}{4}$ h.p. B.S.A., which is quite new and has only run a few miles.



A rubber tube conveys the acetylene gas to an auxiliary jet inserted in the top of the carburetter.

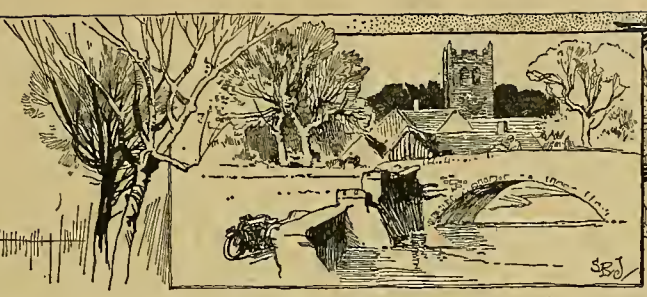
No Need for Petrol.

As the day when we inspected the device was cold, the engine was very stiff and starting was not particularly easy. The machine had to be pushed to start, which it succeeded in doing after the third attempt. Immediately the gas had started to generate, the water was turned off and the engine at once fired, the paraffin smoking a little as it did so, but probably when warmed up there would be no smoke at all. Mr. Passey is so pleased with the success of his device that he has decided to fit it to standard makes of carburetters. He will fit a standard carburetter with a jet for 12s., and supply a complete outfit with generator for 22s. 6d. With this device there is no need for petrol at all, as the machine will start on the acetylene and fire the paraffin immediately afterwards. Mr. Passey also claims to run about 50% more mileage to the gallon with paraffin than with petrol.

MEETING OF THE 17th W.D. VOLUNTEERS.

A meeting of the motor cycle section of the 17th W.D. Volunteers at Owler Bar, near Sheffield. It was the final run for three of the members, who are about to leave for active military duties, and after operations the members unanimously decided to make them a presentation in the form of a roll containing articles useful on active service. (Inset) Commander Riley on a Clyno outfit leaving the meeting.

Lightweight Transmission.



A COMPARISON OF THE VARIOUS METHODS IN USE.

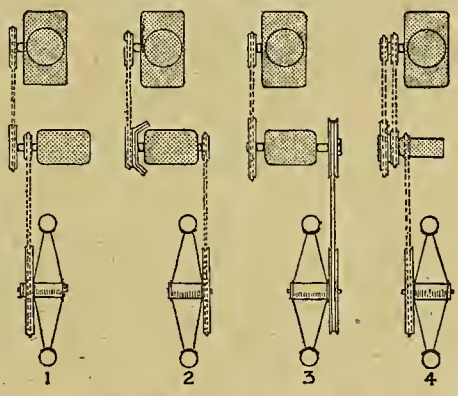
I HAVE recently been sampling transmission systems on various lightweight machines, and have come to the decision that a combination which does not appear to exist would be about ideal—namely, chain-cum-belt drive with a friction gear on the lines of the Enfield. The existing two-speed systems may be set down as follow:

1. All chain, with gear box only.
2. All chain, with gear box and clutch.
3. Chain-cum-belt with gear box only.
4. All chain, with friction gear.

Simplicity, Foolproofness, and Cheapness Essential.

My present lightweight is all chain with gear box only, and so far as my own use is concerned this little machine leaves nothing to be desired. But a lightweight should be essentially a machine which any juggins can ride, and therefore the gears should be foolproof. It is really astonishing what gears will stand, but it makes one shudder to see the uninitiated idiot, after missing his gear, allow the machine to come almost to a standstill, then slam in the low gear with the engine racing. Therefore the system, excellent though it is in the hands of a rider who knows how to "wait for his engine," falls short of permanency in that it can be atrociously bungled by the novice.

SIMPLE SKETCHES OF PRESENT TRANSMISSION SYSTEMS.



No. 1 shows gear box only; No. 2, gear box and clutch; No. 3, chain-cum-belt; No. 4, tri-chain gear.

Next on the list is the all chain drive with gear box and clutch. This is all right so far as it goes, but there are so many conflicting opinions as to whether or not a clutch is necessary on a lightweight machine that the system is hardly likely to hold its own against the combined gears and clutch (friction gear). It seems to me that the only important point in favour of the separate clutch is that it can be controlled from the handle-bars, and a properly tuned lightweight will run so slowly that this is superfluous.

Then again, we are adding complications, weight and cost. A clutch, to be of any real use, must be of certain dimensions which do not fit in with the compact and diminutive measurements of the permanent lightweight, and an inefficient clutch is a thousand times worse than none at all. There are, unquestionably, one or two lightweights with this form of transmission which leave little to be desired, but judging the system from an entirely unbiased standpoint it would seem to me that it falls short of permanency. Simplicity, cheapness, and absolute foolproofness are the necessary constituents of the permanent lightweight, and it would appear that this system is ruled out on all three.

Smoothness and Controllability.

We come now to the chain-cum-belt with gear box only, *i.e.*, no clutch. In this case the belt performs a valuable function in that it absorbs the nerve-racking shocks which occur when the rider, in changing gear, does not wait for his engine. But that the shocks *do* occur, and that shocks cost money whether or not they are partially absorbed, is obvious. The lightweight rider will always include the learner and the unteachable, and in the majority he will not possess that fine judgment necessary for changing gear on a solid drive.

All chain with friction gear—Enfield system. This is the best I have come across, on account of the foolproofness and smooth engagement of the gear, but I prefer the final belt drive in the case of lightweight machines, because it is absurdly cheap to run. The arguments against the chain-cum-belt system when applied to a heavyweight lose their force when the system is applied to a lightweight. Therefore I think that the friction gear in combination with the belt drive would be very near the ideal, and it would mean that the strain on belts and tyres would be so greatly reduced that their wear would be almost indefinite.

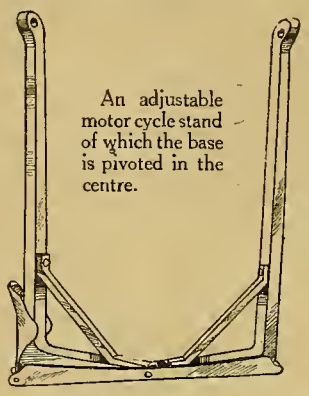
Then, of course, there is the huge advantage of having a free engine position from which one can make a standing start if through bad surfaces or an up gradient such a proceeding is necessary.

Summing up, then, I have criticised no particular system, but all of them, and have recommended one which does not appear to exist. The friction gear is, in my opinion, undoubtedly the best for lightweights, not only on account of its absolute foolproofness, but on account of its convenience and simplicity. Its use does not require that fine judgment which only experience can give to the rider—experience which a large number of lightweight riders will always be without. Whether or not it be combined with a chain-cum-belt or an all-chain drive is, perhaps, a matter of personal tastes.

H.M.B.

AN ADJUSTABLE MOTOR CYCLE STAND.

TO stop and stand a motor cycle on a slanting pavement or side hill is impossible at times with the ordinary stand, as its base will take the position of the sloping surface. The



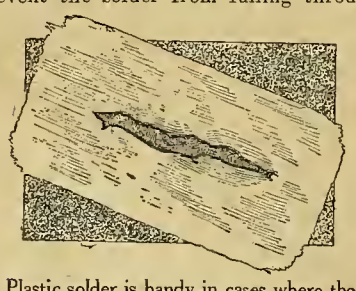
An adjustable motor cycle stand of which the base is pivoted in the centre.

stand illustrated has been designed to overcome this difficulty, and, since practically all England is engaged upon war work, it is almost unnecessary to state that the device emanates from America.

The base of the stand is pivoted in the centre, and a short vertical lever is made to slide on one of the side members. When a machine is pulled up on to this stand, foot pressure on the end of the lever enables the base to accommodate itself to any angle of the road, and compensates for any grade, thus keeping the machine upright. A stand of this character is really wanted on sidecar machines, which when on the stand usually are resting on one leg only.

PLASTIC SOLDER.

WE have lately been putting to a test some plastic solder sent to us by Mr. A. P. Bevan, of Willestrew House, Tavistock, Devon. With this solder it is possible to mend quite large holes, and we show herewith a sketch of an actual repair. The gash measures 32×4 mm., and has rough edges, but the solder has effected a sound repair. It was applied without any support to prevent the solder from falling through.



Plastic solder is handy in cases where the ordinary metal could not be used.

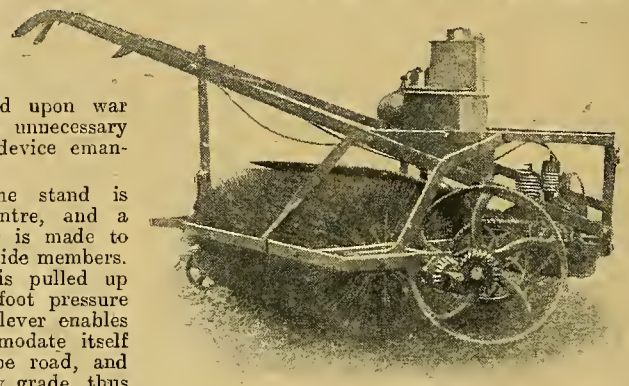
If the soldering iron be not too hot, the solder takes the consistency of putty, and is very easily applied. It should prove most useful for such a job as mending a motor cycle tank.

Mr. Bevan, who is on military service, is anxious to get the manufacture of this solder taken up on a large scale.

AUTO TREBLE-PURPOSE ROAD SWEEPER.

THE principal object in utilising a small-powered petrol engine in conjunction with a road sweeper was to enable one man to carry out the operations of sweeping, tarring, and gritting without additional help. As will be seen from the photograph accompanying, the rear of the chassis carries the rotary sweeping brush, and is cut away from the centre to one side. The grit, tar, and petrol tanks are carried on a bracket above the machine.

The engine is mounted on a platform to the fore, and its power conveyed by means of countershafts to the road wheels and various moving parts. Small-sized



An Auto-wheel power unit is used to propel this treble purpose machine, which is capable of sweeping, tarring, and gritting roads, with only one man in charge. It is a sign of the times to observe the adaptation of a petrol engine to a road sweeper.

road sweepers are guided by an operator walking behind; on larger sizes he is mounted on the machine. The makers, the Road and Street Appliance Co., Greenock, inform us that it has proved entirely satisfactory, even with a small-powered air-cooled engine, though on the larger machines the intention is to fit water-cooled engines.

MAGNETO ANGLE.

ANENT a question published in *The Motor Cycle* recently, a correspondent has sent us sketches showing how he altered a magneto designed for a 50° twin to fire accurately an engine with its cylinders set at 48°. The firing intervals on a 50° twin are 410° and 310°, but as a magneto runs at half engine speed the angles between A and B will be 205° and 155°. The latter angle must be increased to 156° to render the magneto suitable to a 48° twin, and this can be attained by grinding approximately one-third of a millimetre off the cam either at A or B, the points where

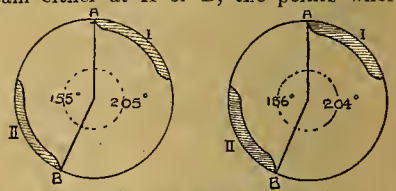


Diagram showing angles between firing points on the contact breaker.

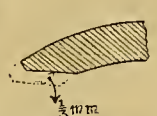
the rocker arm makes contact with the cams. This, of course, must be done very carefully.



The dotted lines show the portion of cam ground away.

AVERAGE PRICES.

WE give below the average prices of second-hand models offered for sale in *The Motor Cycle*. Where it is possible to obtain a sufficient number of each model the average for the past week is quoted, otherwise the last average is given, if within four weeks. Difficulty in obtaining a sufficient number of one particular model often arises, owing to the fact that many advertisers omit some of the most essential details.

Make.	Year.	H.P.	Average for last week.	Latest weekly average obtainable.

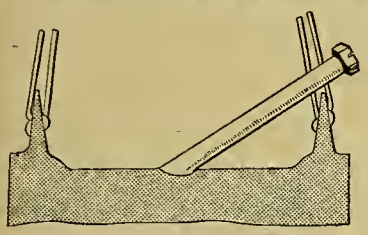
THE LATEST 8 h.p. SUNBEAM

Improvements and Refinements in the Sunbeam Military Machine.

RECENTLY we paid a visit to the works of Messrs. John Marston, Ltd., for the purpose of seeing a large consignment of sidecar stretcher carriers just completed for the British and French Red Cross Societies. The stretchers are fitted to 8 h.p. Sunbeam machines, the sidecar chassis being similar in construction to the ordinary touring model, except, of course, as regards springing.

Our illustrations convey a fair idea of the outfits, which, it will be recalled from an account in our Christmas Number, are performing excellent work in connection with the British Ambulance Unit working in conjunction with the French Army in the Vosges. The stretchers can be removed from the chassis or remounted in a few seconds, the attachment being



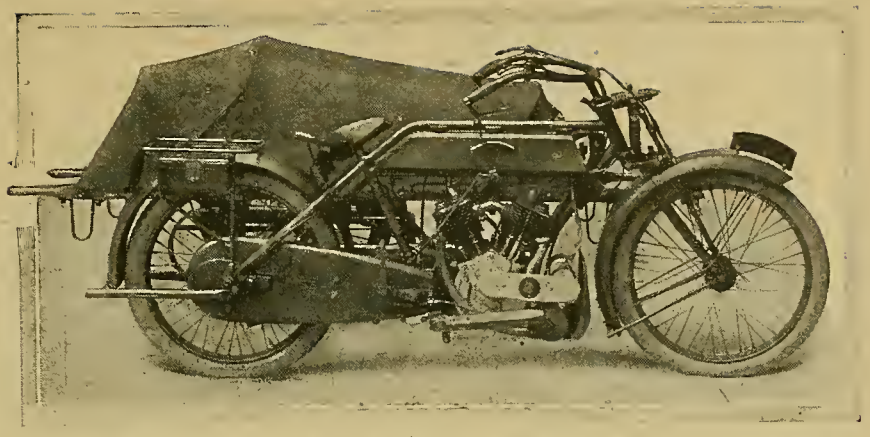
A tube is extended through the wheel spokes, so that oil can be conveniently forced into the hubs by an oil gun.

by means of a very simple locking device, brought in and out of action by the movement of four small levers placed at the points of support.

All the machines supplied for the British Red Cross Society are fitted with Parsons non-skid chains on the rear wheels.

Increased Ground Clearance.

A very large number of Sunbeam machines are still being supplied to the various Governments, and at present the works are concentrating on an order from the Russian Government for forty-five machines per week. All these are the famous 8 h.p. model, half the order being for sidecar ammunition boxes and the other half for ordinary sidecar outfits.



The latest 8 h.p. Sunbeam has 28in. × 3in. tyres, increased ground clearance, wider mudguards of dome shape, and many detail improvements.

The military model 8 h.p. J.A.P. engine Sunbeam differs from the touring model, with which our readers are familiar, in several important points of design. In the first place, a minimum ground clearance of 6in. is provided, this being obtained by slightly raising the frame, so that the top bar takes a rather deeper fall to the saddle, and also by fitting 28in. wheels and 3in. tyres. The fitting of these large wheels is, we consider, an excellent point, and particularly desirable in the case of a military sidecar machine.

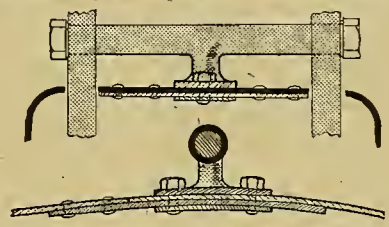
Detachable Wheel and Clutch Improvements.

All the wheels are, of course, detachable and interchangeable, and the original design has been simplified and refined. By simply loosening off one nut the wheel spindles can be drawn out, this allowing the wheel to fall without further trouble.

The plate clutch contains double the original number of plates, the gripping surfaces being phosphor bronze to steel. The plates are now drilled instead of being provided with oil grooves, as in the original model—a much better arrangement, since the oil grooves were apt to accumulate dirt and became filled up, so that the clutch required occasional dismantling and cleaning. Besides requiring less attention, this clutch is even more perfect in operation than its predecessor, being remarkably sweet in engagement, and when properly home the drive is almost positive.

Lubrication.

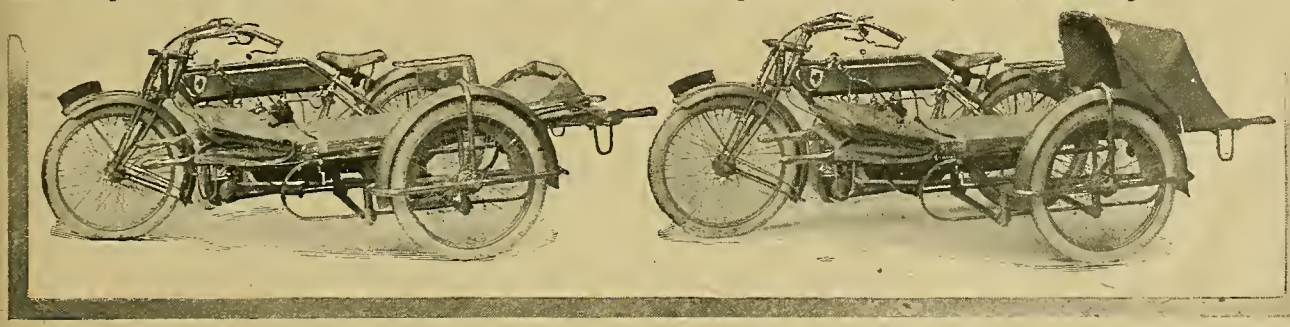
Rotherham grease cups are used for all minor bearings in place of oil cups, and a highly practical arrangement for lubricating the wheel hubs has been adopted. As shown in our illustration, a tube projects from the centre of the wheel hub, the end of this tube, which protrudes just through the spokes, being



Section of front wheel mudguard. The manner in which the two sections of the guard are attached and suspended from the forks.

sealed by a hexagon-headed screw, which is provided also with a slot so that it can be removed either with a small spanner or screwdriver. Every machine is equipped with an oil gun, so that stiff oil can be forced into the bearing *via* the tube. This convenient and thoroughly practical method of lubricating does away with the awkward and unclean business of inducing inadequate quantities of oil to enter by the usual small orifice.

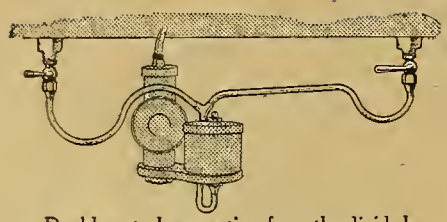
Another point of design, which can hardly be regarded as one of insignificance, is the new design of front wheel



A specimen of the present type of 8 h.p Sunbeam stretcher carrier as supplied to the British Red Cross Society and to la Croix Rouge Francaise.

The Latest 8 h.p. Sunbeam.—

mudguard. The guard is about 8in. in width, enclosing the fork stays and the brake, and giving very ample clearance for the tyre. This guard is almost flat, but the edges are domed over to prevent mud escaping from its interior, and, since it encloses the forks, it must, of course, be in two sections. The attachment, however, is strongly made, the guard being suspended from the frame at this point by a substantial lug which forms part of one of the fork struts. It is inconceivable that such a guard could become clogged, even under the most trying conditions.



Double petrol connection from the divided tank to the carburetter.

The tanks of both models are now partitioned laterally, each partition having a capacity of 1¼ gallons on the 8 h.p. and 1 gallon on the 3½ h.p. models. Separate leads are taken to the carburetter—a very convenient arrangement for those using heavy fuels.

The Sunbeam people are certainly putting their military experience to good practical use, the outcome of which will undoubtedly be the production of a machine meeting the demands of every practical rider, whether at home or abroad. Though the whole of the factory is employed on war work of one kind or another, there is every sign that steady development and perfection of detail are going on, so that we can cheerfully anticipate a post-war model *par excellence*.

A Dutch Endurance Test of 558 Miles.

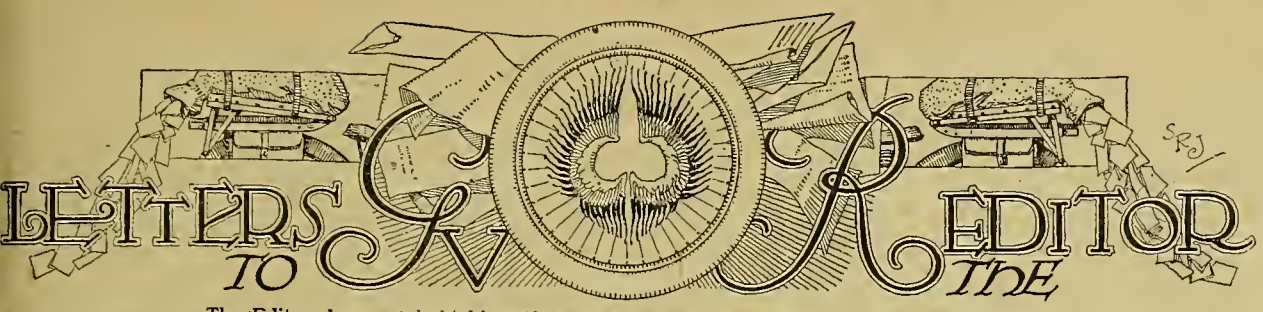
(Top) The American Excelsior military team at Amersfoort.

(Right) Martin C. van de Wal (7 h.p. Excelsior, on the left), winner of the special prize for completing the distance without rest.

(Left) Lt. Bolton (2¾ h.p. Douglas), who finished successfully. This British mount was easily the lightest of the eleven surviving machines.

IN all kinds of unpleasant weather and road conditions several winter motor cycle reliability trials have been held in Holland. The last was of a particularly strenuous nature, consisting of a continuous test of thirty-six hours, in which regular running to a schedule was the chief condition. A circular course was plotted out of approximately ninety-three miles, which had to be covered six times, giving a total distance of 558 miles. Among the twenty-one starters three rode British-made machines, viz., Sun, Rover, and Douglas, the latter, ridden by Lt. Bolton, completing the course successfully, and showing the ability of a 2¾ h.p. machine to follow 7 h.p. mounts in all weathers.

Among the competitors were two military teams, one riding Harley-Davidsons and the other American Excelsiors. Rain and snow were encountered during the run, and many experienced nasty falls owing to the unspeakable road conditions. Only half the competitors successfully completed the course. A special prize offered to riders making the best performance and taking the whole course without rest drew two competitors, the winner being Martin C. van de Wal.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

ARMY MOTOR CYCLES FROM THE FRONT.

Sir,—After the war, what will become of the hundreds of motor cycles now in use at the Front? It is hardly probable that the Government will retain all of them, even if sound in wind and limb.

There will, without a doubt, be a mass of motor cycling enthusiasts after the war who will search your columns for their particular fancy. I can see a great danger looming ahead with regard to the second-hand mount; for example, the 1915 model which has been carefully stored during the war and the 1915 model from the Front. What a difference there must be between the two mounts, yet they will probably appear identical in the advertising columns, and how is the prospective buyer to distinguish between them?

If all, or part, of the machines from the Front are bought by dealers, who, after a slight overhaul, glut the second-hand market, the private man will suffer. The great danger to the buyer lies in the hidden defects in the machines which have been ridden at the Front, which, although not apparent when bought, would show themselves after two or three months' usage, and, consequently, the reputation of the makers will be at stake through no fault of their own. The buyer's safety will also be at a discount if he gets hold of a machine which has been ridden at the Front and patched up for sale. If the different firms who have supplied the Government with motor cycles will repurchase them the solution is easy; if not, I can see chaos and disaster in the second-hand market.

ALFRED CLARK.

THE CASE FOR THE LONG STROKE.

Sir,—I have not followed all the previous discussion which has appeared in your valuable paper on long *versus* short stroke engines, but have just read with great interest my friend Mr. Norton's excellent article, "The Case for the Long Stroke." He certainly makes out such a good case for his splendid long stroke motor that many people after reading his article may jump to the conclusion that all engines with a stroke equal to, or approximately equal to, the cylinder bore were designed by men who did not know their business. Nothing could be more erroneous. Mr. Norton makes the somewhat dogmatic assertion that it is never necessary to run the long stroke engine at so high a speed as the short stroke to develop equal power. This has not, to my knowledge, ever been conclusively proved. The fact that no motor bicycle with a short stroke engine of equal capacity has hitherto equalled the wonderful performances of the Norton on Brooklands track does not absolutely prove this assertion.

After having been mixed up with the design, construction, and testing of successful engines of all types during the last fifteen years or so, I firmly believe that it would be possible to build a square engine (bore equal to stroke) with overhead valves to equal and probably surpass the Norton records.

In comparing long with short or medium stroke engines of equal cylinder capacity, Mr. Norton somewhat grudgingly admits that the latter have certain advantages not possessed by the former, viz., the short or medium stroke engine is lighter per unit of power, and that at high rates of revolution its bearing pressures are less. Therefore, I may be mistaken, but I venture to assume that if Mr. Norton were called upon to design a high-powered aero engine which has to fulfil the following three conditions: (1) Maximum compactness of power unit; (2) *minimum* weight per horse-power, which, in itself, necessitates power being developed at a high r.p.m. with a high volumetric efficiency; (3) highest possible degree of reliability—we should then see the *medium* stroke Norton competing with some of the best aero motors in the world which have a bore and stroke ratio of approximately 4¾in. to 5in.

J. T. CLARKE.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—It is quite apparent, without any careful study, that your correspondent, Mr. Addenbrooke, has not had a sufficient experience with the flat twin to realise all its good qualities, when we read his ideas of the engine fixing not being secure enough to avoid pulling over towards the driving side.

We beg to point out to him the method with the most popular 2¾ h.p. model now in the market, and also the "slide rest" type of engine fixing applied on the 4 h.p. of the same make; this absolutely *does* prevent any possibility of his mythical trouble.

Having had a fairly varied experience with the points he mentions we can emphatically say that if the engine is fixed in the frame vertically in the first place when the machine is assembled, it will be found that after all the gruelling it can be put to (and it gets it here, Wiltshire) it has not shifted at all.

May we also ask, if Mr. Addenbrooke judges a motor cycle from his own ability to drill holes in the radiator fins of his cylinders, whether he has been in the habit of so doing, and for what reason? He will find, if he looks round, that all the cylinder fins of better class machines made of cast iron are, by a special process in the casting, left hard, or brittle, as he calls it, partly perhaps owing to a special mixing of the metal, and the fact of its being cast by people who *do* know just what this important part of a motor cycle should be.

We must, whilst fully realising the sterling qualities of the A.J.S. machine, differ from him in his claims of it having the most silent timing gear on the road, and ask him to have another look round, see, ride, and generally study the principles of design of other machines, and then perhaps he will realise that the Americans are not far off being there every time; also the M.A.G., etc., which, although we do not agree with all Mr. de Lissa's ideas, is undoubtedly a very fine example of engineering in this respect. The 4 h.p. Douglas also cannot be called a serious offender in the matter of timing gear, being quite as quiet as the one Mr. Addenbrooke mentions, yet not "the most silent on the road."

The usual disclaimer in cartloads.

WILLIAM MULLIS.
ARTHUR COPE.
S. A. MARKS.

"The Motor Cycle Shop," A.S.C., M.T.

Sir,—I do not quite see the logic of "R.E.C.'s" statement that the fact that there are more parts does not help to make a breakdown! What are the chief causes of trouble on the road?

(1.) Plug trouble. It is obvious at once that the more plugs are used the more chance of sooting up, or oiling up, etc. Twin cylinders, twice the chance; four cylinders, four times the chance; and so on.

(2.) Broken piston rings. Every cylinder added to the engine must mean an extra chance of this occurring.

(3.) Seizing up of the piston, or broken piston, broken connecting rod, or trouble with the small end bearings—it is again obvious that the same argument applies.

It is common to hear the single spoken of as a "jerky" engine; but if one considers that at an average speed of 2,000 r.p.m. there are no fewer than sixteen power strokes a second, it will be seen that the four-stroke single compares favourably with an ordinary steam engine of the same power, as evenness of torque, of course, depends solely on power strokes per unit of time, and even an "eight stroke" single (if there were such a thing) would give a torque even enough for all practical purposes if it could be run economically at double the revolutions per minute as a four-stroke single.

The old bugbear of extra wear on tyres and transmission with a single compared with a multi-cylinder was exposed long ago. I get over 2,500 miles from my back covers before they require retreading, and I do not think that can be bettered by any twin. Nearly all my work is with heavy loads in the sidecar.

The only case I have had in five years of chain breakage was on a two-stroke twin. Of course, if riders will overgear a single and let the revolutions down so as to cause tugging, they must expect trouble with wear. Also, it is common to see some riders attempt to crawl round a sharp corner at little over walking pace on top gear to save the trouble of changing down (not much trouble with a Sturmey-Archer countershaft gear!). This, of course, is rough on the engine and tyres; but, if driven with a little intelligence, always "keeping the revolutions up" whatever the gradient, there will be no undue wear.

MICHELMORE HITCHCOCK.

Sir,—Though following with great interest your columns anent the "Single *v.* Twin," I did not intend to enter the ranks of the inkslingers, who so steadfastly uphold the cause of their particular choice. But "Yorkshireman" in your issue of December 28th has altered my decision.

What he, in common with hundreds of others, does not, or will not, realise is that, quite apart from the type of machine to which it is fitted, or the purpose that machine is required to fulfil, the *gear box of to-day is made to be used!* His phrase, "The rider can almost regard his two lower gear ratios for emergency purposes only," to my mind, entirely spoils his letter.

It might have rung true in the days when so-called "gear boxes" were unreliable, flimsy contraptions, with which one took the risk of a stripped pinion with each change of gear; but the present-day reliable gear box of first-class make—and the "dud" ones are now few and far between—is made just as much to be used as that of a car.

If a car driver hangs on to top he is called chosen names and branded an idiot. Why, then, should a motor cyclist differ?

"Yorkshireman" must realise that the possession of a four-speed gear box brings us one step nearer to the motor car—surely the ideal of the motor cycle designer. Apart from which fact the delight of using intelligently a gear box, as apart from making a machine "a demon for top gear pulling," seems to be realised by a strict minority.

The fact of using one's gear ratios is not—as "Yorkshireman" seems to think—a drawback, but one of the greatest advantages of the motor cyclist. PROGRESS.

Wolverhampton.

KICK-STARTER FOR ZENITH.

Sir,—For some years in South Africa and this country I have been an interested reader of your valuable paper and have come to the conclusion that some one of your many readers will probably be able to help me out of a difficulty.

I have a 6 h.p. Zenith (standard) of, I think, 1912 model, which is somewhat heavy to push in order to start. I have written to the makers asking their views as regards converting the machine to a kick-start and clutch model, but they inform me that the cost of conversion would be too great.

I have no desire to sell my present Zenith, as I cannot afford a new machine. Could any of your readers suggest a method by which I could attach a hand or kick-start, and approximate cost?

I have thought of a new wheel with separate driving pulley and a hub gear, but do not know if I could obtain a wheel with a spindle of 10in. which is required on a Zenith.

I should be grateful to any reader who could help me out of this difficulty. J. HARRY McEWEN.

Nairobi, British East Africa.

ELECTRIC LIGHTING FOR MOTOR CYCLES.

Sir,—I noticed some time ago in *The Motor Cycle* an article on electricity for lighting purposes, which greatly interested me. I have now fitted up head, width, and tail lamps to my sidecar machine. I am running them off a 30 ampère hour ignition accumulator, four volt, which is giving me about fourteen hours light. I have an ordinary head lamp with adjustable holder, in which I run a .5 ampère miniature screw lamp as used in pocket lamps, and have run my width and tail lights in series (2.5 ampères each), so that by looking at the road by my sidecar I can tell if the tail light is in. I have made my own width and tail lamps out of old electric switch lamp holders, and the whole outfit, including the head lamp, has not cost me 30s. I am getting sufficient light to do riding on the N. Wales roads after dark, and until recently have not been troubled with the lamps. I charge my own accumulator at home, so that, with the assistance of your paper, I have rigged up a cheap lighting outfit, which is highly satisfactory.

H. COOPER.

A PLEA FOR SILENT MOTOR CYCLES.

Sir,—One reads and hears a great deal about post-war models of motor cycles. I sincerely hope that the new models will be several times quieter than the average existing model, particularly as far as the single-cylinder is concerned. For many years I have taken a great interest in motor cycles, and am myself an engineer, but I must say that, if I had my way, at any rate, the average single-cylinder motor cyclist should be heavily fined every time he goes out for the abominable noise made from the exhaust of the machine. No doubt a number of motor cyclists will scoff at this idea, but I can assure them that a great deal more harm is done to the motor cycle movement from the noise of the machine than anything else. The average layman speaks of motor cycles as "those noisy things," and for once the average layman is correct. Incidentally, the foregoing remarks are applicable to the correspondence you are publishing, referring to the single-cylinder vertical engine against the horizontal twin, and, if from no other point, the horizontal twin is a vast improvement on the noisy vertical single. A.M.I.E.E.

London.

MUDGUARDING.

Sir,—It is refreshing to see you continually hammering at the manufacturers to produce a better mudguarded machine and so keep the motor cyclist clean when motoring.

I have had a new 4 h.p. single for eighteen months, and the one and only thing I have against it is the front mudguarding. In the winter I fix up my own mud shield and discard it for the summer, but going down to business the other morning after a night's rain I was slushed up to the knees before I had travelled a mile.

It is exceedingly aggravating to have to put up with such crude mudguarding when a better could so easily be adopted without spoiling the appearance of the machine.

I have no alternative but to motor cycle to business, all weathers (five miles), and have decided to try some other make of cycle if the makers of my machine will not give better protection against mud from the front wheel than the system at present used.

Considering the times through which we are passing, your paper loses none of its interest—a great credit to the organising staff. J. RYCROFT.

OUTSIDE FLYWHEELS.

Sir,—Noticing with interest the different letters appearing in *The Motor Cycle*, dealing with the comparisons on flat twins and 500 c.c. single-cylinder engines, I should like to ask a question.

It is generally admitted that the fitting of an outside flywheel on an engine goes a long way towards making it easy starting and smooth running. As the outside flywheel is fitted on flat twins and the greater majority of baby two-strokes, why is it that there are not more 500 c.c. singles similarly fitted?

In Capt. Lindsay's letter in your issue of December 7th he said, "Watch a Blackburne turning over in neutral."

Surely, then, it would be equally advantageous to fit an outside flywheel on similar 500 c.c. singles to remedy the "snatchiness" of drive complained of by numerous riders.

Sherborne. A.H.S.

VALVES AND EFFICIENCY.

Sir,—Engine efficiency is often ascribed to overhead valves, but I do not think that this is always the case. I possess a 1912 3½ h.p. Premier with extra exhaust ports. This I run with a coachbuilt sidecar, and I have taken my wife over Llanberis Pass without a falter during a tour in North Wales—in fact, none of my friends owning 3½ h.p. machines can keep with me, and I can give a 6 h.p. machine "a run for its money." It may be argued that the Premier machine holds no records, but that does not trouble me.

The usual disclaimer. LK 1810.
Peckham.

SIDECAR V. CYCLE CAR.

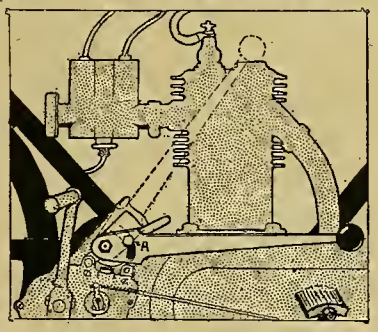
Sir,—After two years of enthusiasm for the cycle car, I have come to consider my old mount—a sidecar combination—the best. There is something far more fascinating about the posture on the saddle and the grip of the bars than sitting down lazily in a car seat. Then, too, the height of the saddle gives a far better view over hedges both of the road ahead and of the scenery around. Again, unless one is settled in a house where one can rig up one's own garage or is near a convenient proprietary garage, the detachability of the sidecar is useful. The possibility for the conveyance of extra passengers at odd times for special occasions is also much better on a sidecar outfit. To improve the sociability, I think of rigging up a special sidecar seating which will decrease bodywork, and so make for increased accessibility, too.

Will your readers kindly give me, c/o the Editor, their opinion of the 3¾ h.p. Scott with sidecar attachment? It so happens I have met this machine but little in close acquaintance. IVOR E. MERCER.

STURMEY-ARCHER GEAR CONTROL.

Sir,—May I point out that all Sturmey-Archer gears can have the gear control position shifted in ten seconds or less to suit either hand or foot control by the mere slackening of a stud? I enclose a sketch of what I mean.

P. J. LINDEN,
Lt., A.S.C., M.T.
B.E.F.



By loosening the stud A the gear change lever of a Sturmey-Archer gear can be adapted to foot control. (See letter from Lt. P. J. Linden, A.S.C., M.T.)

WHY DOES THE ENGINE CARBONISE?

Sir,—May I make a few brief and simple observations on the above subject? Free carbon, for such is the deposit in petrol engines, is found in many forms, such as soot of all kinds, charcoal, graphite, etc., and is the result of decomposition by heat. Large quantities of free carbon, similar to that in question, are found in gas tar. This is due to the decomposition by heat of the tar oils on the hot sides of the retort. It is therefore certain that carbon in petrol engines is largely due to decomposition of the lubricating oil. The more generous the lubrication the greater the deposit.

As regards fuel, the less perfect the combustion (as in the case of a smoking lamp) the more carbon is produced. Most of us are familiar with the black exhaust of a rich, or imperfect, mixture. The colour is entirely due to particles of carbon, and it is only reasonable to suppose that a good deal of it adheres to the piston and cylinder, especially when they are moist through lubrication or imperfectly vaporised fuel.

Conclusions.—The prevention of carbon deposit is impossible. Excessive deposit is caused by (1) over lubrication, (2) too rich mixture principally through reduction of air to prevent knocking, (3) carburetter not adapted to fuel (practically all carburetters are tuned for petrol No. 1), (4) hot engine, and, in the case of petroil engines, (5) the petrol helping to burn the lubricating oil.

If the above suggestions are correct a water-cooled engine will carbonise less rapidly than an air-cooled engine.

"Ixion" and others will be interested to know that I have had a Lodge plug in my Triumph since 1913. It has run well over 20,000 miles and, as far as I can remember, has only sooted up twice. During this time three spares have worn out by friction in the bag. FREE CARBON.
Leicester.

HEATING THE CARBURETTER.

Sir,—Being one of those who take a good deal of interest in the various experiments described by various correspondents in *The Motor Cycle*, I think perhaps one of my own experiences may interest you, more especially as it seems to me rather extraordinary, and a direct contradiction to commonsense and science.

The machine I ride is a heavy 4¼ single-cylinder combination. I have nothing but praise for the behaviour of the engine, often under trying circumstances, and solo the machine is wonderfully fast, without any special tuning, and is very economical in the way of petrol. In pre-war days I used benzole neat, when I could get it. At present I have to use the liquid designated as petrol, but I also use an equal quantity of what is, I believe, a low grade benzole, the addition of the latter being absolutely necessary to bring the present-day No. 1 petrol up to the same standard of pulling power as the old pre-war No. 3.

I may say in passing that I have run on half petrol and paraffin, also on pure paraffin, though the latter was only for short distances, and I don't think much of either.

Long ago I thought of a kind of air scoop to the carburetter, but I did not experiment in that direction until one day a friend of mine suggested an arrangement of that nature to help, if possible, to compensate for the inferior quality of the petrol. I then rigged up a sort of shield to help direct air on the valve pockets and convey the heated air to the carburetter, so that the engine drew hot air not only through the extra air inlet but also through the main air inlet. I took great care that the free passage of air was ensured. On trying the attachment I found no apparent advantage; in fact, I thought it a disadvantage, so I set to work and made another and more perfect attachment, but to my disgust I found the engine ran hot, knocking on the slightest provocation and refusing to take anything but the mildest of hills, and I fancy the consumption went up considerably, but of this I cannot be quite sure. At first I thought that perhaps the cooling of the valve pockets was interfered with by the air scoop or shield, or whatever you may call it, so I removed this, but obtained no better results. I then replaced that portion and removed the tail end so that the engine drew in cold air as usual, with the result that things became normal again, proving that the cooling of the valve pockets was not the trouble.

I may say I was running on petrol only at this time; weather conditions were good, the experiments being made in July and August.

Shortly after this I saw a description in *The Motor Cycle* of an attachment identical with mine fitted to a Triumph, and which gave very excellent results. Now I quite believe it did give good results in the other case, and I know it ought to have given good results in my case, but the fact remains it did not do so. I wonder if any of your readers ever found that their engines run better on cold than on hot air? I may say that on ordinary occasions my engine is not given to running hot.

There has been much writing about heating the induction pipe, and I am sure this is quite right where a long induction pipe is used, but with a short pipe, when the carburetter is close up to the cylinder, surely heating is unnecessary. In my case, after a very short time running the carburetter (a B. and B. of the new type) gets nice and warm, and I am quite sure the petrol is thoroughly vaporised before it gets into the cylinder. When one comes to think of it, surely the petrol must vaporise thoroughly after passing (even in large drops) into a hot valve pocket, and thence through a small circular slit past a hot valve head into a still warmer cylinder. I will admit the time occupied by the petrol in passing from the jet to the cylinder head is very short, but then the passage is very hot, and after all even third grade petrol is a highly volatile substance, or rather liquid.

H. H. BROWNRIGG.

[Owing to the large number of interesting letters received weekly, many have to be held over for want of space. Correspondents are therefore asked to be brief and to the point.—ED.]

THE EXISTING LIGHTING REGULATIONS.

A Review of the Conditions applying to Motor Cycles.

THE lighting regulations with which motor cyclists must conform are now more uniform throughout the country, and are as follow:

If lamps with fronts exceeding 6in. across are used, the fronts must be so covered that light can only pass through a central portion not exceeding 4½in. in diameter. All electric and acetylene lamps (including the central apertures of head lamps reduced as described), and all candle or oil lamps with lens fronts, must be obscured, as at present, with at least one thickness of ordinary white tissue paper or an equivalent medium.

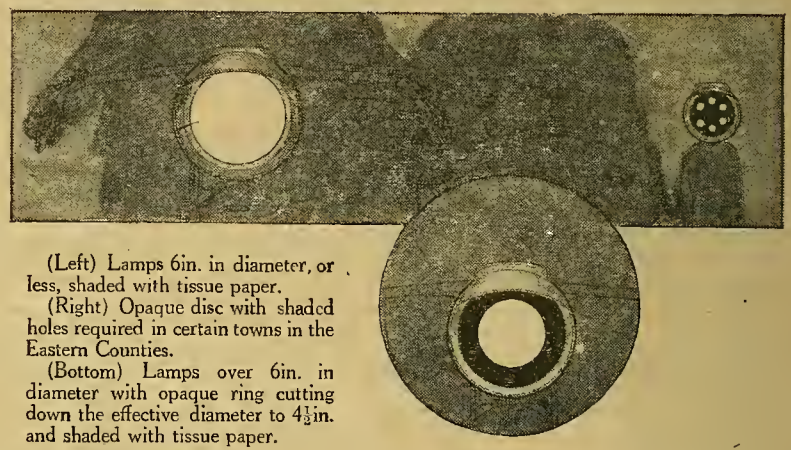
The special restrictions which apply at present in certain towns in the Eastern Counties remain unaltered—that is to say, the disc with six holes must still be used on electric and acetylene head lamps and on oil and candle lamps with lens fronts.

The six holes referred to must be circular, half an inch in diameter, and must be spaced equally around the opaque disc in such a manner that no portion of any of the apertures is nearer the centre of the disc than one quarter the diameter of the effective front of the lamp. Tissue paper or its equivalent must be used to cover the holes.

The area covered in the Eastern Counties by the special restrictions referred to was illustrated in *The Motor Cycle* of January 13th, 1916.

No light of any description on any vehicle which is at a standstill may be visible from the sea or the navigable waters of any estuary.

THE THREE ALTERNATIVE METHODS OF SUBDUING LAMPS NECESSARY ON MOTOR CYCLES.



(Left) Lamps 6in. in diameter, or less, shaded with tissue paper.
(Right) Opaque disc with shaded holes required in certain towns in the Eastern Counties.
(Bottom) Lamps over 6in. in diameter with opaque ring cutting down the effective diameter to 4½in. and shaded with tissue paper.

THE PETROL POSITION IN IRELAND.

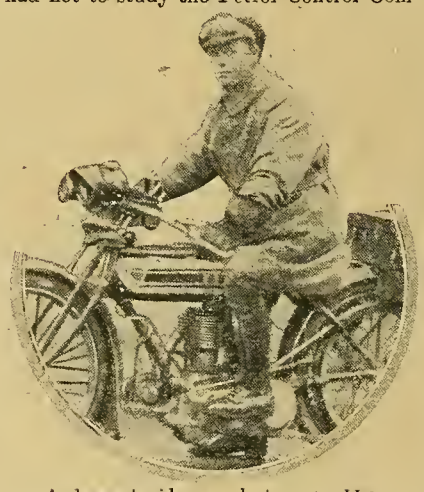
AS a considerable amount of misconception appears to exist in regard to the regulations governing the supply of motor spirit in Ireland, it may be well to set down the present position of affairs for the benefit of local motor cyclists, as well as for those who may visit the country on business.

Briefly, it may be said that the regulations are similar to those in force in other parts of the United Kingdom, but there is the additional requirement that the permits to purchase petrol issued by the Petrol Control Committee must be endorsed by the military authorities.

Previous to the Petrol Control Committee's scheme coming into operation there was a very serious shortage of spirit in Ireland. One day none would be available in Dublin or Belfast. A week later it would be plentiful in both places, while in towns and villages between the two cities not a drop would be obtainable. These periodical shortages were due to the irregularities of the sea-borne supplies, coupled with the fact that the shadow of the coming of the permit system caused every user of the spirit to do his best to secure a supply in anticipation of the possibility of a real shortage.

With the introduction of the permit system in August all difficulties with regard to supply disappeared. Dealers found a reduced demand, and stocks began to accumulate, not only in the hands of the retailers, but also with the wholesale distributers. That state of affairs prevails to the present time, so that the motor cyclist who has a Petrol Control Committee permit, and is in a position to satisfy the military authorities that he has a legitimate use for the spirit, experiences no difficulty in having his permit endorsed and getting all he is entitled to in any town or village in the country.

There is little doubt that in Ireland, as in other parts of the kingdom, a good deal of petrol has been issued since August last that was not authorised by the Petrol Control Committee. The Irishman—as not infrequently persons of other nationalities—often finds a loophole to get outside or around the law, and he had not to study the Petrol Control Committee's system very deeply to find out its weak spot. While he is not authorised to supply motor spirit without the production of a licence, and it is required to enter thereon the amount of spirit supplied, there is no obligation on him to keep a record of his sales, or to enter the amount of spirit he received from the wholesale distributers. There is a recommendation of the Petrol Committee to do so, but recommendations are not always respected.



A despatch rider attached to the Heavy Section, Machine Gun Corps, the section operating the armoured-car Tanks. Harold Hughes, the rider in question, was formerly in the Motor Machine Gun Service, and has seen eighteen months' service.

Military Control.

The need for further control of the petrol supply by the military authorities arose because of the recent rebellion. There was a fear that petrol might get into the hands of persons who would supply it to enemies of the country, and use it for improper purposes, and to prevent this it was considered necessary to have the permits endorsed by the military authorities, who, in turn, delegate their powers to the police. At first this system of having petrol permits vised existed only in a few districts, and these, for the most part, in places where, under any circumstances, it would have been difficult to get any large quantity of spirit. An Order of the Army Council recently issued extends the system to the whole country, and county and district inspectors of the Royal Irish Constabulary and superintendents of the Dublin Metropolitan Police have been authorised to act for the military authorities. It may be added that the Army Council Order does not require the dealer to keep a record of the petrol he sells or gives away—a distinct loopbole in an otherwise comprehensive scheme.

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Engine Refuses to take Air.

(1.) As soon as I open the air lever of my 3½ h.p. machine it slows down and stops, unless I open the throttle and go 20 m.p.h. What is the remedy? (2.) Is 4¼ to 1 too high a gear for a 3½ h.p. solo single-speed machine? What should the ratio be? (3.) I cannot run more slowly than 8 m.p.h. What can I do to run at 5 m.p.h.? (4.) Knocking occurs at all speeds with levers in all positions.—L.A.B.

.) The trouble is probably due to air aks at the carburetter or induction pipe nions, or owing to a worn valve guide. ry excluding the air, or fitting a slightly rger jet. (2.) 4¼ to 1 is rather too gh; 4⅜ to 5 to 1 would be better for a ngle-gear machine. (3.) With a single ear you cannot hope to run very much ore slowly than 5-6 m.p.h., firing regurly. (4.) Have you tried cleaning the rbon deposit from the cylinder recently? f course, the knock may be simply ppet noise or noise in the valve gear. such be the case it is incurable. Too uch air is quite likely to cause the ngine to knock, though if the knock continuous it would rather indicate adly-worn engine bearings.

Distribution of Weight on Sidecars.

Will you please inform me as to the correct distribution of weight when fitting a sidecar? I have always been under the impression that the passenger's weight should be over the sidecar axle, although I have noticed on some of the combination outfits that this is not so by any means. In these cases the front attachments are, perhaps, much stronger. I do not want to run the risk of the front attachments giving way for the sake of simplifying the steering a little. As my sidecar is fixed at present, I experience difficulty in taking a right hand turn. Sometimes I can feel the front wheel skidding as it were under the machine. I presume there is a certain amount of drag on every sidecar outfit when taking a right hand turn. What do you consider the best distribution of weight?—E.E.S.

'he weight distribution of sidecar bodies a knotty problem. The sidecar body laced too far over the sidecar axle auses poor steering, while if placed too ar forward throws great strain on the ront connection and bicycle frame and orks. If the machine is sufficiently trong and connections are stout the forward position is perhaps preferable. Of course, a happy medium is what is wanted, and exactly the best position can only be arrived at by personal experiment. Unfortunately the natural design of a sidecar outfit is such that there is always a tendency for one wheel to drag sideways. If carefully lined up it is the front wheel of the bicycle which will scrape. This, of course, affects the steering. The best plan is to line up in such a way that the sidecar wheel is running *slightly* toward the machine. This gives better all-round steering and less side pull, while the extra wear on the sidecar tyre, caused by the tendency to scrape, is less than it would be on the steering wheel when the sidecar is lined up absolutely parallel.

Sparking Plug Position.

When I first purchased my 1914 second-hand single-cylinder the sparking plug was over the exhaust valve. Later on, when adjusting the engine after starting difficulties, I changed it over to the inlet port, after looking at a sketch on the cover of "Motor Cycles and How to Manage Them," which showed the plug in this position. Now, after again adjusting the engine to locate a mysterious misfiring, and "blowing back" through the carburetter, I have moved the plug back to its old position over the exhaust, and for the first time have noticed a marked increase of speed and power and absence of misfiring. What is the correct position for the plug, and am I wise in placing it over the exhaust valve?—H.S.M.

There is no doubt that the proper place for the sparking plug is over the inlet valve. If placed over the exhaust valve it is subjected to too much heat. The symptom which you describe is, in our opinion, quite inexplicable. It may be accounted for by the fact that the gas which passes the plug points when situated over the exhaust is drier than that which passes the inlet valve position. There is no doubt that the plug should behave better over the inlet valve. However, if it answers better over the exhaust valve there is no harm in leaving it there, provided you do not eventually burn out the points. It is doubtful whether your plugs will last any length of time.

SPORTSMEN'S USE FOR A MOTOR CYCLE.

A buck brought down within twenty miles of Duluth, Minn., as the result of a three-hour hunt. The motor cycle and sidecar have become very popular with sportsmen in the States, as the machine enables them to reach the hunting grounds easily, while the sidecar serves to transport their equipment to the woods and the game back to the city.

Pre-ignition.

(1.) I recently purchased a 1913 3½ h.p. Humber motor cycle and sidecar, and have been using petrol substitute, and have been troubled considerably with irregular running and overheating. The engine invariably stops after about two miles, behaving as if it had seized, but it will always start up immediately afterwards. What is the cause of this? I do not think it can be through want of oil, as I have been rather over-oiling. I have also had the carburetter down and cleaned it thoroughly. (2.) Ought the low-speed pedal of the Roc two-speed gear to "catch on" similarly to the high-speed pedal?—W.G.W.

(1.) It looks as if the trouble were not due to the use of petrol substitute at all, but to the plug causing pre-ignition. Use a good single or double-point plug with fairly substantial electrodes. To obtain good running with petrol substitutes the air entering the carburetter should be warmed, and the engine should be perfectly clean inside. Make sure the piston rings are free in their grooves. (2.) No, the low-speed pedal is kept in engagement merely by the pressure of the foot.

Gear Adjustments.

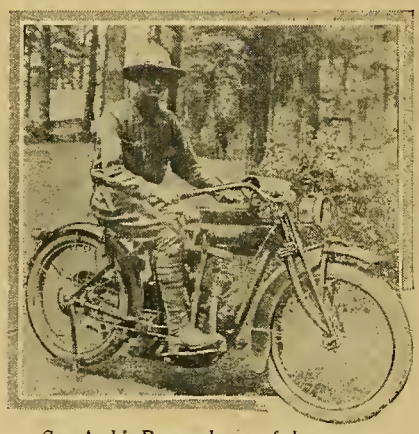
I have a 1910 Triumph fitted with N.S.U. gear. It seems difficult to get any information on the overhaul, adjustment, and care of these gears. Owing to the big number of N.S.U. gears on the road, the information you could no doubt give would be of great value. (1.) Is the centre keyway in the shaft for adjustment purposes? If so, how is it adjusted? (2.) How is the pulley adjusted? (3.) Is sperm oil right for lubricating? (4.) How can I prevent "racing" of the engine on top gear at speed? Up to 15 m.p.h. everything is right, but above this "over-running" seems to set up. I do not think it is belt slip.—E.G.L.

(1.) We take it when you speak of the "centre keyway" that you mean the square hollow in the centre of the gear shaft behind the operating bar? If so, this is not for adjustment. It is simply the continuation to the nut that secures the whole gear to the engine-shaft. It is done up or undone and the gear removed or fixed by means of the square projection on the special spanner usually supplied with the gear. (2.) If the pulley is of the adjustable pattern the back flange is the adjustable one, and is locked by means of a locking flange. This has to be slackened, probably by means of a hammer and punch. The flange can then be screwed either in or out for expanding or contracting the pulley. (3.) Ordinary engine oil is best, and should be injected through the hole closed by a screw provided for the purpose on the side of the gear. (4.) The following are usually the causes of top gear slip on these gears: *(a)* Top gear cone worn and bottoming; remedy, new top gear cone clutch. *(b.)* Main spring weak, requiring renewal. *(c.)* Operating bar too tight a fit, and preventing the top gear clutch going fully into engagement. When the gear lever is screwed fully into top gear the operating bar should be quite free, and it should be possible to turn it round or swivel it easily with the fingers, that is, there should be clearance between it and the operating fork. If this is not so it is holding the gear out slightly, and requires reducing a little in size, or the operating fork grinding so as to give clearance when the top gear is engaged. This is a very common trouble. By operating bar we mean the small crosshar on which the operating fork wedges. Try washing out the gear with paraffin, and filling it with fresh thick oil. Make sure the belt is not slipping.

High Petrol Consumption.

Recently I purchased a 1911 3½ h.p. Triumph, and find that I can only run thirty miles on one gallon of petrol. This is my first motor cycle, therefore, as a new reader, I seek your advice. (1.) Would a smaller jet cure this? (2.) Is there anything else that would cause this excessive use of petrol? The tank and connections are quite tight. The late owner informed me that the machine was very low geared. (3.) From what points on the pulley and belt drum do I measure to get the gear ratio?—W.R.B.

(1.) A smaller jet should cure the trouble. Also go over the petrol system carefully, and eliminate all chances of leakages at the unions, filler caps, carburetter joints, etc. (2.) Of course, if the machine were low geared, this would help to account for the high consumption. To obtain really good consumption, the whole machine needs to be in really good order. Go over the engine, and see that the valves are in good order and the compression good. In driving, always give as much extra air as the engine will take, and keep the spark as far advanced as possible. (3.) Simply leave the belt in position, jack up the back wheel, turn it round, and count the number of revolutions the engine pulley makes to one revolution of the rear pulley, and this will give you the gear accurately.



Sgt. Archie Roosevelt, son of the strenuous Theodore, as despatch rider at the business men's training camp, Plattsburg, N.Y. Our American cousins are not slow to adopt the useful lessons of the great war, judging from the extensive orders recently placed for motor cycles for despatch carriers, machine gunners, etc., not to speak of orders for armoured cars and aeroplanes.

READERS' REPLIES.

Kidderminster to Selsey.

I noticed in a recent issue of *The Motor Cycle* that you gave a route from Kidderminster to Selsey, in which you advised going through Bishop's Waltham, Fareham, Cosham, etc. I consider it would be better and much shorter to go from Winchester to Petersfield, and thence through Midhurst, Cocking, Singleton, Lavant, and Chichester. The roads are in good order considering the time of year; moreover, the run would be much more pleasant.—BK 3075.

Refusal to take Extra Air.

I think "G.E.C.'s" trouble is certainly in the tappets, for exactly the same thing happened to my 1911 3½ h.p. single, only in this case the tappet adjuster had dropped off, thus leaving far too much clearance, so that the valve was losing nearly half its lift. I hope this may be helpful to "G.E.C."—MALCOLM G. HALLOWES.

Slip in an Enfield Gear.

I am interested in the question and reply to "E.A.F." in the issue of December 28th, and rather fear your explanation is not quite what "E.A.F." wants, because you dismiss the vital point in exactly the same way as the Enfield Co. In their book of instructions it is said that, after removing the thrust bracket, "the cam can easily be pulled out." This, however, is not always the case, and I think "E.A.F.'s" trouble is that he is afraid to strain something by forcing. Even when the low gear is engaged to its fullest extent the cam is still gripped by the actuating peg and needs force to release it. If "E.A.F." will insert a screwdriver behind the face of the thrust bracket he will find this gives just sufficient extra pull on the low gear to release the cam.—W. KAY.

RECOMMENDED ROUTES.

WELLINGBOROUGH TO GOLDER'S GREEN.—G.W.C.

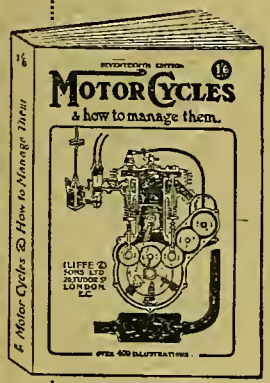
The Seventeenth Edition

of

MOTOR CYCLES

& how to manage them.



The most complete work of the kind ever published

376 Pages. **425** Illustrations

Carefully revised, re-written throughout, and much enlarged. Many new features.

¶ Service riders will find this book an indispensable companion . .

Price 1/6 Net.

By Post, Home or Abroad, 1/10.

Obtainable from THE PUBLISHERS, ILIFFE & SONS LTD., 20 Tudor St. London, E.C. and all leading booksellers.

PATENT

TRIPLE WINDSCREEN

WITH the side wings closed, the passenger rides in complete enjoyment and security from draughts and dust. A touch allows the screen to swing open out of the way of the alighting passenger. Adjustable to any angle, the screen is very easy to fit, and suits almost every make of car. The side wings can be detached.

In Polished Walnut with Nickel Fittings:

Price complete with Side Wings £3 0 0
Price of Single Screen £2 2 0

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted Series discounts and special terms to regular trade advertisers will be quoted on application

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., & Co. and crossed

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20 Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisemeot. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

New Imperial.

COLMORE Depots, Manchester and Leicester, for immediate delivery of New Imperial motor cycles. [0805

IMPERIAL-J.A.P., 1916, 2-speed, perfect; £43.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [7191

RIDER TROWARD, 78, High St., Hampstead.—1915-16 New Imperial, 2-speed, mileage 2,500, as new; 27 gns. [7320

NEW Imperial-Jap, 1916, 2¾h.p., 2 speeds, splendid condition; sacrifice £26/10.—436, Whitehorse Rd., Thornton Heath. [7378

J. A. STACEY, 12, Ecclesall Rd., Sheffield, for Imperial-Jap, the finest lightweight on the market; delivery from stock. [6246

NEW Imperial, 1916, 2-speed, with speedometer, lamps, etc., new tyres, in excellent condition and running order, almost new; £28.—Lieut. Lockwood, 21, Avenue Rd., Brentwood. [7136

NEW Imperial, 2½h.p., 2-speed model, £40/10 2-speed, clutch, and kick starter model, £48/6; easy purchase terms if desired; exchanges entertained.—Harrods, Ltd., Motor Cycle Dept., Brompton Rd., London, S.W. [7212

Norton.

1916 3½h.p. Norton, all chain, 3-speed countershaft, lamps, horn; £56.—Smith, Baker, Wateringbury. [7206

1915 Big 4h.p. Norton, new November, 1915, 3 speed countershaft gear, splendid condition throughout; any expert examination, or reasonable demonstration; sacrifice for quick sale at 55 gns.—H. M. Charles, Chessington, Stoke Green, Coventry. [X4667

N.S.U.

N.S.U., £9/10, mag., B. and B., Brampton variable pulley, head and tail lamps, 3h.p.—Watson, Greenways, Hook. [7198

N.U.T.

N.U.T., 2¾h.p. twin J.A.P., 3-speed gear, tyres good; £25.—Morrison, John St., Langholm. [7264

O K.

O.K.'s in stock, M.A.G. £42/10, J.A.P. £38.—Youngs, 2 and 3, The Parade, High Rd., Kilburn. [6931

O.K., 1916, 4-stroke, 2-speed, countershaft, elaborate accessories, spares, and tools, as new; £25.—Heed, 31, Hainthorpe Rd., West Norwood. [0867

Omega.

1916½ Omega, 3h.p., 2-speed, 2-stroke, done 500 miles, will take sidecar, spare petrol tank, vaporiser, excellent condition; take £33.—A. Maddock, Springfields, Alsager, Cheshire. [7156

P. and M.

P. and M., 3½h.p., 2 speeds, in good order; a bargain, £15.—Percy and Co., 337, Euston Rd., London. [7421

P. and M., 1909, 3½h.p., 2-speed, new sidecar body, aluminium footboards, spare tank; £19/10.—J. Bowen, 29, Jersey Terrace, St. Thomas, Swansea. [7160

P. and M. Combination, 1914, 3½h.p., and P. and M. sidecar, lamp and horn; £55; deferred terms if desired.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [7223

Peugeot.

3½h.p. 1913 Pengeot, Bosch, B. and B., good tyres, belt, lamps; £20.—61, Peckham Park Rd., S.E. [7143

Precision.

PRECISION Engine, 2¾h.p., Sturmey-Archer 3-speed gear, free engine, clutch; £28.—M. Shanks, Downham, Norfolk. [X4499

2¾h.p. Torpedo Precision, B. and B., adjustable, Bosch, done 3,000 miles, 160 m.p.g., splendid condition; £19.—Rhodes, 8, Ash Grove, Weaste, Manchester. [X4690

Premier.

PREMIER, 1915, 3½h.p., 3 speeds, countershaft, kick starter, coachbuilt sidecar; £44; in nice order.

PREMIER, 1913, 3½h.p., 3 speeds, coachbuilt sidecar, perfect order; £29.—Percy and Co., 337, Euston Rd., London. [7410

1914 4h.p. 3-speed Premier, in perfect running order; £25, lowest.—Chapmans', Engineers, Hurlingham, S.W. [7200

1913 Premier, 3½h.p., Philipson pulley, sound condition; £20.—Montgomery, Victoria Rooms, Bristol. [X4257

PREMIER, 1914, 2¾h.p., excellent condition, Gradogear; £21, bargain.—Wheldon, 251, Barking Rd., East Ham. [7269

1914 3½h.p. Premier, 2 speeds, coachbuilt sidecar; £45; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0823

1914 Premier, 2½h.p., 3-speed, clutch, all accessories; £24.—Smith, 16, Haverstock Hill, opposite Chalk Farm Tube Station. [7397

1914 3½h.p. Premier, 2-speed, handle start, Bosch mag., head and tail lamps, new tyres, splendid order; £33.—A. H. Ellis, Wivenhoe, Essex. [7381

Preferential Treatment for Front Cylinders.

IN another part of this issue we describe an arrangement which has for its object the equalising of the explosions in either cylinder of a V twin, the idea of the designer being that, owing to the inertia of the gases, they would be left behind in the induction pipe and consequently fed more freely to the rear cylinder. That this action would take place to some slight extent at the moment of acceleration is, of course, quite obvious, but in the paragraph referred to we give reasons why this action should not continue when the machine settles down to a steady pace. It has been stated that the petrol in a cylindrical tank placed transversely will bank up at the back to some extent and remain in this position so long as the car retains its speed, as shown by the level of the petrol in the gauge. We cannot agree, however, that the two cases are analogous, for there is no disturbing influence in the tank to cause the petrol quickly to resume its natural position, but in the induction pipe the gases are flowing rapidly first in one direction and then in the other, leaving the carburetter in every case at a velocity equal to that of the motor cycle.

Every railway traveller knows that when the engine starts his back is pressed against the cushions for a moment as the train gains speed, if he is sitting with his face to the engine, but that this sensation is not continued; moreover, when a piece of paper is thrown across a railway carriage it is not left behind so long as it is in the carriage, but as soon as it passes through the window and meets the outer air its speed, equalling that of the train, is at once arrested by the air resistance, and it is left behind. All motion is, in fact, relative. The contention of a natural surging of gas to the rear cylinder is not without interest, however, but if it could be substantiated the action would surely have been countered ere this in car engine design, where induction pipes are naturally much longer.

Future Petrol Allowances.

WE have already hinted that when the present petrol licences expire in April the allowances to motor cyclists may be reduced. No details as to the plans of the Petrol Control Committee have yet been disclosed, except that it has been definitely stated that the monthly grants will not be increased. When the Petrol Control Committee first began to get to work in August last, motor cyclists were allowed the merest pittance of petrol. When winter arrived and the new licences came into force a more reasonable allowance was made, and motor cycling, that most healthful and beneficial of pastimes, could be carried on, as it should be carried on in war time, in moderation. It has been hinted that at the present moment there is petrol enough and to spare after the needs of the Services have been supplied, but that the proposed restrictions are intended to force economy on motorists so that they may have more money to lend to the country. Looking at it from the motor cyclist's point of view, it is difficult to see how much more they would be forced to save by having their petrol allowance reduced, or even stopped altogether. The money actually paid for petrol would be saved, it is true, but the 1s. tax levied on every gallon would be lost, and the amount left for motor cyclists to put into the War Loan would be infinitesimal.

It has always seemed to us that the control of the sale of petrol, so long as there is plenty for everybody, has been grossly unfair. No distinction is made between the man who uses his machine for business and the man who rides for health and pleasure only. The doctor and veterinary surgeon are rightly given all they require, but the road surveyor, the commercial traveller, the clergyman, and the journalist get no consideration whatever.

We all want to finish the war off quickly; will it be prolonged if we use petrol? We venture to think not.

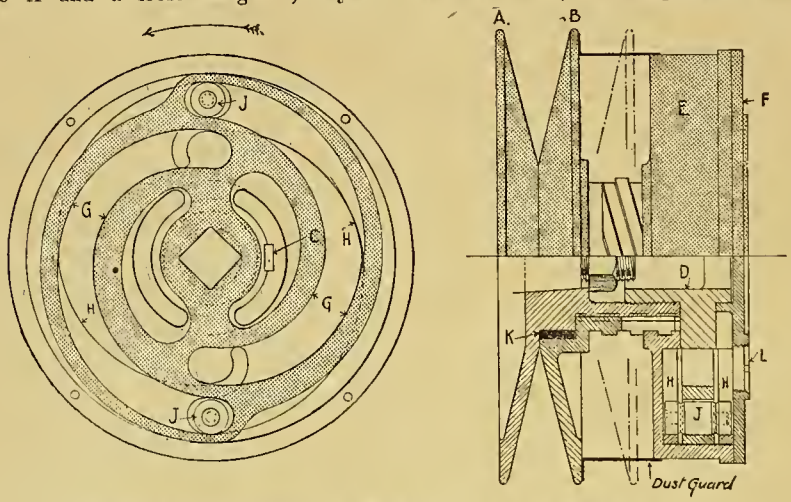
An index to the advertisements in this issue will be found on the page facing the back cover.

AN AUTOMATIC GOVERNOR PULLEY.

A Device which alters the Gear Ratio in Proportion to the Power and Resistance.

AN ingenious automatic pulley has been invented and patented by Mr. H. L. Brooke, of Bradford. It can be made in three forms, that which we describe is preferred by the inventor; the other two are partly controlled by springs, but the principle is in the main identical.

The V belt pulley consists of a fixed flange A and a loose flange B, keyed together by a feather key C, which permits the loose flange to slide. To the boss of the fixed flange is attached a part D, and on the boss of the loose flange is a suitable thread, engaging a thread on the boss of the governor pulley E, which has a cover F. Part D has grooves G, and the inner faces of governor E and cover F have curves H, which are duplicates of each other and of the outer faces of grooves G. Pins J pass through the grooves G, and engage curves H, and are designed to have rolling contact with the said grooves and curves.



Brooke's governor pulley, the details of which are described in the accompanying article.

Correct design depends upon the shape of the outer faces of grooves G and of the curves H. Differential rotary motions of the governor pulley E, relative to the V belt pulley, will cause the loose flange B to move to or away from the fixed flange A, according to the direction of the differential motions. It may be noted that, as drawn, one complete differential revolution of the governor pulley E is possible. The force tending to move the belt pulley to the top gear position, as drawn, is the centrifugal force generated in pins J, which causes them to roll along grooves G and take the pulley E with them. The force tending to move the belt pulley to the low gear position (loose flange shown by chain lines) is the impulses of the engine acting against the inertia of the governor pulley E.

It must be noted that the *normal position* of the belt pulley is top gear position, as drawn.

The balancing of the two opposing forces that control the governor pulley E, it is claimed, constitutes a true governing action, all increases of power not giving equivalent increase of speed, as when climbing, causing a correct reduction of gear ratio and *vice versa*.

It is proposed to design the pulley so that normal position of top gear be obtained under normal conditions at an engine speed of about 700 r.p.m. It may be accepted that normal conditions mean running on the level.

Claims.

We have not tried the pulley, but flexibility is claimed under all conditions. The grip on the belt is ensured by the constant tendency to move towards top gear. Low gear at low speeds, for starting, or whenever needed, is automatically obtained, because the small centrifugal force in the pins at low speeds would not resist the light impulses of the engine.

The full power of the engine is obtainable without reduction of gear if there is equivalent increase of speed.

Screws L are shown to enable different sizes of pins to be inserted. Simply changing the size, and *therefore the weight*, of the pins would be equivalent to a complete change of average gear ratio between the engine and tractor wheels. The smaller the pins the higher the engine speed relative to machine speed. Thus, if a certain size of pin made a machine suitable for solo work, a smaller size would make it suitable for sidecar work, by reducing the *average* speed of the machine relative to power and speed of the engine, thus preventing overstrain of the engine.

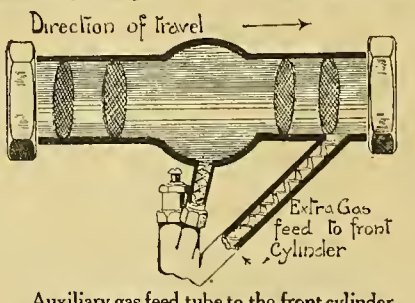
Finally, reduction of gear tends to permit increase of engine speed, which, in turn, would tend to return to top gear, there being a true governing action. *Top gear would be normal*, all other positions being the result of changes in the relationship of power and speed.

VALVE TIMING ON TWINS.

Should the Front Cylinder have Preferential Treatment?

IN our description of the new Harley-Davidson we mentioned that the valve timing was not the same in each cylinder. A variation in the timing is not by any means a new idea, and we remember that, years ago, Mr. Norton stated that better results could be obtained by some such modification. The same principle was used nearly two years ago in a petrol consumption trial in America, in which it is claimed that H. Cameron covered 91.2 miles on two quarts of petrol. His machine was a twin Indian, and he ran throughout on the pilot jet with gauzes in the induction pipe. This answered well at slow speeds, but when going fast the front cylinder ceased to fire. Cameron therefore fitted an extra pipe to give an easier path from the jet to the front cylinder, and this overcame the difficulty.

The explanation given is as follows: "The gas and air are heavy. When the motor cycle lurches ahead they quite naturally surge towards the rear, just as so much water would surge to the rear if it were in the manifold in place of the mixture."



Auxiliary gas feed tube to the front cylinder of a 7 h.p. twin. This arrangement facilitates even firing whilst running on the pilot jet.

Personally, we do not think the explanation is sound, nor that there would be any surging to the rear except when the machine was accelerating. At a constant speed the inertia of the gases would prevent the effect described, for, while the gases were passing up the pipe from the pilot jet, they would have a forward velocity equal to that of the machine, and this velocity would be maintained in the induction pipe unless they met with some outside resistance, which they could not do. As it is stated as a fact that the extra pipe improved the running, we should be inclined to attribute the result to a leak somewhere in the induction system of the front cylinder.

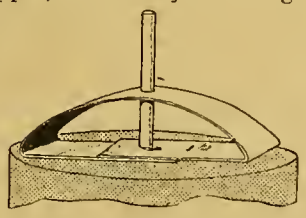
Occasional Comments by "Ixion"

The "Ben"—R.I.P.

MANY a motor cyclist felt a real pang when he read last week that the dear old *Ben-my-Chree* had been sunk by gunfire in the Mediterranean; indeed, the Admiralty intimation was the first some of us had heard that she was doing her bit as a seaplane carrier. For the benefit of the uninitiated, I should explain that the "Ben" was the greyhound of the Manx steamers, and robbed the T.T. of half its terrors for many of us. She could do the seventy miles from Liverpool to Douglas in just over three hours, and, as one enthusiast put it on a day when all the smaller boats were rolling and pitching, "She has a good front fork, and her rear springing's extra!" We still hope the submarine caught her in shallow water, and that she can be salved. Oh dear! Shall we all have to cross in the *Lenella* for the first post-war T.T.? We felt less regret when another of the Manx boats, the *Ramsey*, was sunk by gunfire in the North Sea; for it was a steep-sided narrow boat, with a nasty knack of rolling on the least provocation; and, thanks to her, many of our readers have paid for dinners which did not benefit them.

A Carburetter Detail.

I ILLUSTRATE herewith the ingenious detail by which the petrol level is maintained on some carburetters. It is really self-explanatory. The bent strip is made of copper, and has just enough spring to keep the two holes in the overlapping ends out of register, and so lock the clip on the float needle. If the two ends of the clip are pushed inwards with thumb and finger, the holes register and the clip slides up or down the needle easily. One of these clips came handily to my rescue the other day; the carburetter which I was using had a split pin above its float, and the pin had commenced to gape a bit with age and many removals, so that it would come clean off the needle whenever I ran the engine hard. With this clip I was able to get a firmer setting.



Float needle clip referred to in accompanying article.

Overhead Valve Engines and Tune.

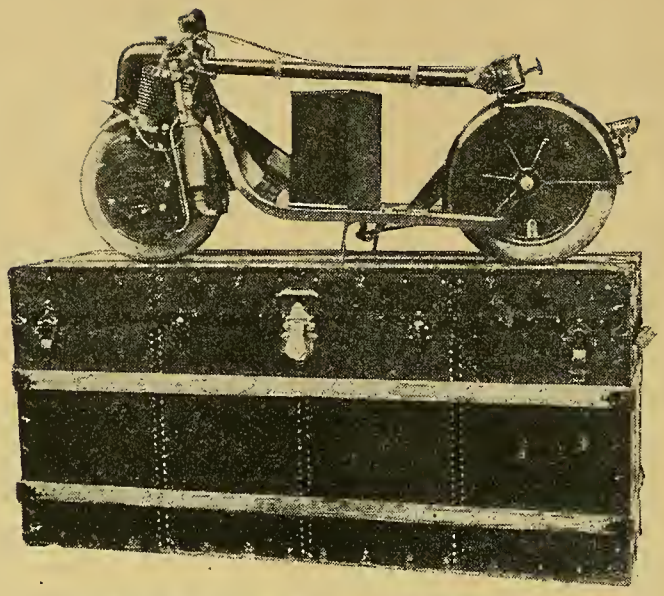
UNTIL the M.A.G. engine, with its enclosed overhead valve mechanism, came along, it was unquestionably true that overhead valve engines kept their tune badly. The cams and tappets of the side valve engines suffer from wear that is microscopic in character; the one exposed point is the clearance between valve stem and tappet, and on the average engine that point is automatically lubricated—I had almost said over-lubricated. On the o.h.v. engine there are four exposed points at which wear may be expected, the bottom of the long tappet, the top of ditto, the rocker pivot, and the rocker tip. The first of these is automatically lubricated, as stated; the other three are unlubricated on many engines. The tips of the rocker cannot be lubricated on many o.h.v. engines, and in some cases the pivot bearing cannot be kept oiled either. Wear at all these points piles up, until a fraction of wear at each point affects the valve timing quite considerably. On other engines the adjustments for this wear are flimsy, and it is not easy to set them with perfect accuracy; so that one is perpetually fiddling with tappet adjustments. The best method of furnishing a little makeshift lubrication at the points under criticism is to dab a spot of graphite grease between the wearing surfaces; it will not last indefinitely, but it retards wear, and it makes for silence.

The Franklin Piston.

LIKE most makers of air-cooled engines, the Franklin Co. are eager to avail themselves of the aluminium piston: first, because it keeps cooler than a steel or iron piston, and engine temperature is of such urgency with air-cooled engine; and, secondly, for the sake of an indirect gain—that the cooler a piston keeps, the less it carbonises. For the same pair of reasons, two-stroke designers are keenly experimenting with aluminium pistons. The Franklin engineers found that, if they gave the new pistons a safe clearance, they "slapped" and rattled; and that, if they reduced the clearance to the silence point, the pistons broke or seized. More oil on the cylinder walls seemed to be the solution, but they did not want more oil at any other point. So they carved a deep groove to wind spirally round the piston between the upper rings and the scraper ring; and this groove retained some surplus oil, and enabled the piston to work with a clearance which forbade any slap, and yet without seizing or smashing. I rather fancy that Mr. J. L. Norton was about the first British designer to utilise oil-retaining hollows on his pistons with a similar end in view. One or two other makers scollop the entire waist of their piston, but I never found that a vague, general recessing of the piston waist served as well as more definite oil-retaining grooves. I remember how, when these things were less understood than they are to-day, I used to file down the waist of my piston, and talk learnedly about piston distortion. I held forth to this effect one day in the presence of a noted engineer, and he said bluntly: "I don't believe in these distorted pistons and high spots; your filing does its work by providing an oil trap!" It is only fair to add that the more maniacal devotees of aluminium pistons deny that they require a lot of oil: and they say such troubles as the Franklin people describe only occur in works where the machining is not accurate to fine limits. Personally, I have owned five or six aluminium pistons: none of them were loose enough to "slap," as the Americans quaintly put it; and all of them wanted lashings of oil.

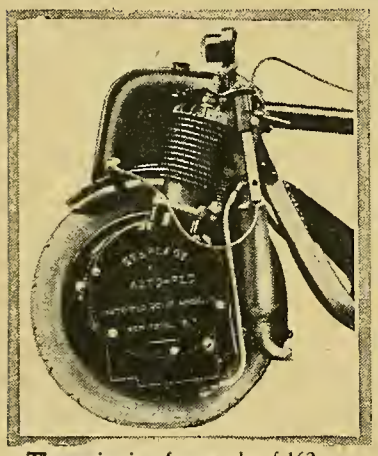
STANDING ROOM ONLY!

THE general tendency in this country is to more comfortable motor cycles and the adoption of spring frames in addition to spring saddles. Our cousins across "the Herring Pond" appear, however, to be made of sterner stuff, if we may judge from the last American importation. Just how it came to be imported we are at a loss to understand with the present ban on all things motorish. Did it come through as a commercial vehicle designed for the use of errand boys, or is the clue to the mystery to be found in one of our illustrations?



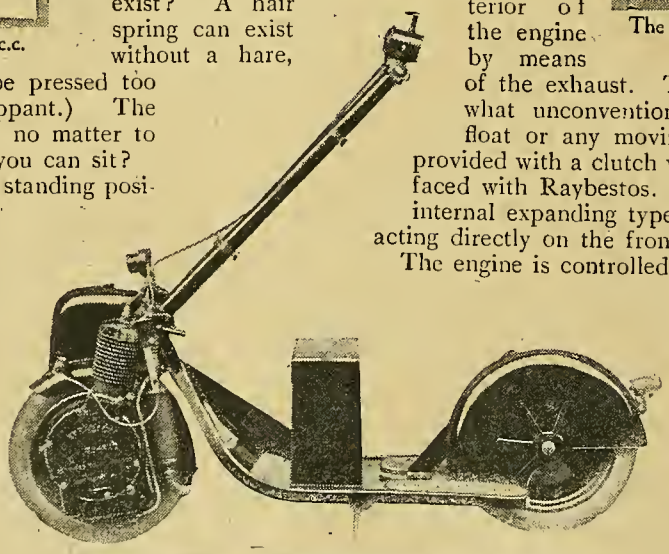
The Autoped and its packing case. Is it a portent of the future? Will the Auto trunk be a necessary part of the luggage when the seaside and promenade are thought of again?

A careful examination failed to reveal any spring frame, and spring saddles appear to be as rare as spring flowers. (By the way, can one spring what does not exist? A hair spring can exist without a hare, but the analogy must not be pressed too far. We must not be flippant.) The absence of a saddle may be no matter to some, but why stand when you can sit?



The engine is a four-stroke of 162 c.c.

On the other hand, in the standing position, we believe that eights and loop threes can be executed with ease and precision, while any skater knows that sitting down is fatal to the graceful performance of these simple figures. It seems a pity that no reverse is provided, for this makes it quite impossible to perform a rocking turn, which necessitates a change of direction but not a change of edge. This would be a most effective figure if done at high speed on a falling gradient, provided that nothing else was failing.

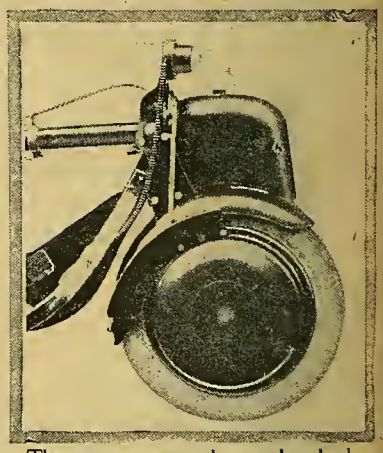


The 2 h.p. "Eveready" Autoped mechanical scooter in racing trim.

THE AUTOPED, AN AMERICAN MOTOR SCOOTER.

Engine Details.

The engine is a single-cylinder four-stroke, 2¼in. bore × 2½in. stroke (162 c.c.). The piston has two rings, the gudgeon pin is of nickel steel, heat treated and ground, running on two hardened bronze bushes pressed into the piston. The connecting rod is a drop forging and fitted with a hardened bronze bush at the crank pin end. The crankshaft is a solid drop forging with the web, counter weight and crank pin forged integrally. It is hardened, ground, and runs on a bronze bush at one end and on a ball bearing at the flywheel side. The engine is lubricated by spraying the oil from the sump into the interior of the engine by means of the exhaust. The carburetter is of somewhat unconventional design, and is without float or any moving parts. The Autoped is provided with a clutch which is of the dry disc type faced with Raybestos. One brake is fitted of the internal expanding type faced with Raybestos, and acting directly on the front rim.



The tea cosy receptacle over the wheel is the petrol tank.

The engine is controlled by one twist handle on the right-hand side of the handle-bar, which raises the exhaust and opens the throttle. The magneto, which is housed completely in the flywheel, is entirely concealed, the only visible part of the ignition system being the cable leading from the inside of the flywheel to the sparking

Standing Room Only!—

plug. The petrol tank is of pressed steel, all joints being welded, and is attached to the front mudguard, while the steering column also acts as an auxiliary tank. This column is capable of being pulled down into a horizontal position and clipped to the rear mudguard, so that it may be stored out of the way, and also used as a handle when it is desired to carry the machine about.

The machine, of course, will be regarded as a motor car or motor cycle within the meaning of the Motor Car Act, and must therefore be registered and carry number-plates, and the owner must take out the usual licences. It also cannot be used until it is fitted with two independent brakes; so far, it is only fitted with one. To mount the Autoped one has to run behind till the engine fires and then step on to the platform.

The Autoped has met with a certain amount of popularity in America, but is practically unknown over here. It is said to be quite suitable for short distances on good roads. The maximum speed obtainable is claimed to be twenty-five miles an hour, but an average speed of fifteen miles an hour is recommended. When not in use it can be packed in a trunk, and may be taken, at any rate in America, as passenger's luggage. The British agents are Messrs. George Newman and Co., 307, Euston Road, N.W., but supplies are not available owing to the ban of motor imports. The few specimens which reached this country were impounded by the authorities at Liverpool.

PORT DESIGNS ON TWO-STROKE ENGINES.

More Complete Scavenging by Increasing the Size of the Exhaust Port and Manifold.

SINCE it is the opinion of many experts that the two-stroke engine is the engine of the future, perhaps a short *résumé* of the principal advantages and disadvantages of this type of engine will not be out of place.

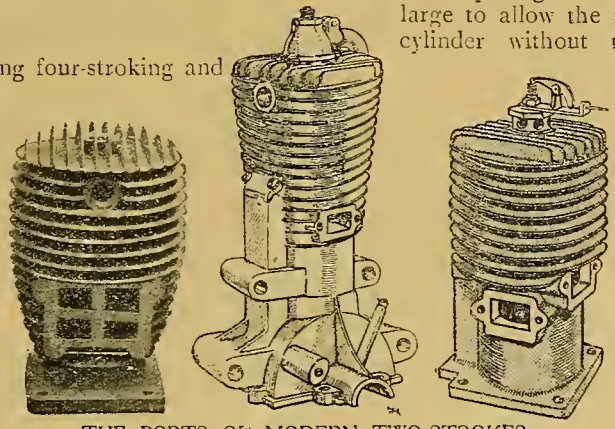
The chief merits of two-stroke engines are:

1. Excellent torque.
2. Good thermal efficiency.
3. Power for weight.
4. Simplicity.
5. Absence of valves.

The principal disadvantages are:

1. Want of flexibility.
2. Difficulty of cooling.
3. Poor scavenging, causing four-stroking and overheating.
4. High petrol consumption.
5. The difficulty of keeping crank case compression efficient.
6. Rapid carbonisation of piston rings.

The list of disadvantages may seem a trifle weighty to one who has had little or no experience of the remarkable practical efficiency of two-strokes. But on many types almost every one of these difficulties has been overcome by patient experimenting and ingenious design. Every day progress is being made by firms who, ignoring the whims of the public, are working to make the two-stroke engine a genuine and permanent success.

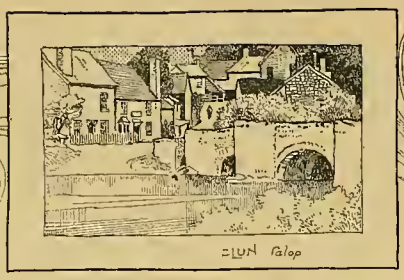


THE PORTS OF MODERN TWO-STROKES.
(1) Connaught two-stroke cylinder, showing combined inlet (at top) and exhaust ports (at bottom)
(2) Allon two-stroke, showing inlet and transfer ports.
(3) The inlet and exhaust ports on the Radco two-stroke.

Two-stroke Defects.

It is to such as these that I would point out the following defect—a defect known and recognised by all manufacturers and users of two-stroke engines from the days of the old two-stroke four-wheelers to the present day, when the two-stroke holds a fair share of the market and might hold more. There being no proper scavenging stroke on these engines, the efficiency of the exhaust depends almost entirely on the area of the exhaust outlet. The design of deflectors on piston heads means much when considering such a question, but the amount of outlet available for the exhaust gases means much more. On many machines I have observed that the exhaust port area was seemingly designed to equal that of the inlet. On many two-strokes a similar resemblance was apparent between the areas of the transfer and exhaust ports. This is *prima facie* absurd, since the new mixture is mechanically forced into the combustion head, and therefore a passage from the crank case sufficiently large to allow the new mixture to flow into the cylinder without undue difficulty would not necessarily be sufficient to pass out hot and expanded exhaust gases under far greater pressure. Larger exhaust ports would in no way interfere with the timing, since the increased dimension would be made horizontally. Difficulties of construction might occur if very much increase were made with some types, but on many of the machines I have examined in this respect quite twice the existing outlet area might be utilised with no other change than an increase in the size of the exhaust manifold. Expense might, of course, keep many firms to their present arrangement, but I think most of the motor cycling public have sufficient confidence in the British motor cycle manufacturers to believe that progress is their policy and perfection their end, even though many considerations must of necessity control their policy and end. The one way for two-stroke makers to show that they mean to demonstrate the permanency of two-stroke popularity is to make their power units equal to four-stroke units in all ways, and superior in those ways which the natural advantages of two-stroke engines bring forth.

PROGRESSIVE.



The Hygiene of Motor Cycling.

A Few Valuable Hints by a Medical Motor Cyclist.

UNDER suitable conditions few sports or pastimes are more conducive to health and vigour, both of mind and body, and at almost any age, than is motor cycling. There are, however, certain risks which riders would do well to bear in mind, especially those of us who have already passed our twenties. I am not referring to accidents, but rather to cases where a lack of knowledge or discretion may lead to what are usually, but not necessarily, minor disabilities and discomforts. Most of the hints I venture to put down here have been suggested to me either by personal experience as a motor cyclist or by the complaints of motor cycling patients and friends.

I know a rider who recently ran short of petrol about two miles from home. Very wisely he left the machine and sidecar in a garden near by and finished his journey on foot, returning at his leisure with petrol in the evening. An acquaintance to whom he related his experience asked him why he did not push the cycle back and so save two unnecessary journeys and a good deal of time. The question was a foolish one, even though some men might have made the attempt, possibly in a few cases with impunity. The incident brings home the fact, however, that any but a lightweight solo mount is too heavy to be pushed for more than a few yards by hand. It is of the utmost importance to remember this. It is as easy to do irreparable injury to that very delicate piece of mechanism the heart when it begins to "knock" as it is to ruin an engine under similar circumstances. When anybody, at any rate anybody over thirty, feels his heart beating rapidly and forcibly after exertion let him take thought and rest. Just as there is a temperature above which an engine may not be heated without permanent damage, so there is a point beyond which the valves and muscles of the heart may not be strained without the same result. To renew an engine is easy, to renew a heart is impossible, and even to repair it may be difficult. Precisely the same considerations apply in connection with the exertion of dealing with an engine which refuses to start up quickly. When your heart begins "knocking" take a rest, and employ the time in calm reflection. Perchance it may occur to you that the petrol tap has not been turned on, or that the terminal at the plug has become disconnected. But, whatever happens in this respect, the risk of personal damage will have been avoided. One does not wish to drive this advice beyond the limits of commonsense, but the point I have raised really needs emphasising with many people. Bearing it in mind may just prevent an excursion into the region of tragedy.

The writer of the accompanying article, who is a medical officer on the Somme.

The Value of Goggles.

How and when to use goggles is another thing well worth considering. A few there be apparently who neither desire, nor feel the lack of, these most comforting appliances, but most of us are less fortunate. Motor cycling may be trying to the eyes in three ways. First, there is the effect of the wind (and of insects or small foreign bodies which may be borne along with it) on the delicate conjunctiva—the stronger the wind the greater the ill-effect. Secondly, there is the strain of keeping the attention fixed, partly on the road ahead and partly on the surrounding objects—the worse the road the greater the strain. Any astigmatism or other abnormality of the lens, of course, is an additional harmful factor. Finally, in sunny or fine weather there is the glare or intensity of reflected light. How severe and painful this may be is best realised by those who have been in such regions as the higher altitudes of Switzerland, where the combination of bright sunlight and perpetual snow obtains. But in summer, glare is by no means to be ignored even in England. Any or all of these causes may have two results. On the one hand, they may lead to aching of the eyes and redness and inflammation of the thin membrane covering their surface. On the other, the headache, which is not infrequent after long and trying rides, may often be ascribed in part to eye strain of one kind or another. As far as anything can do so, a pair of light, well-fitting goggles, tinted if necessary, will tend to minimise or even do away with these discomforts.

Engine Noises.

There is no doubt that some people find the noise of the engine very trying. In my experience, all machines powerful enough for sidecar work are noisy, though some are much worse than others, and even the same machine varies within fairly wide limits. One does not wish to be considered a faddist. I

The Hygiene of Motor Cycling.—

must confess, however, I have found that a plug of cotton wool in each ear adds greatly to the enjoyment and diminishes the fatigue of a long ride, especially in very dry and windy weather. It is the sharp, high-pitched, crackling element of the explosion and the clatter of the valve gear which tend to get on one's nerves.

Weather Conditions.

Motor cycling is one of those sports the devotees of which are at times subject to severe exposure to bad weather. This may be of little moment to the more hardy, but it is not wise for the majority of us to treat the matter too lightly. Seeds sown in the course of a few hours' carelessness may have a harvest in the form of many weeks of discomfort. I have in my mind at the moment a man who set out from Birmingham for a ride which, under the circumstances, took about seven hours. It was raining when he started, and it came down in torrents of almost tropical intensity for the whole distance. In spite of macintoshes he was naturally drenched to the skin. There were no serious results in the form of a definite illness, but for weeks after he suffered from severe neuralgia and rheumatic pains. I know of no way by which he could have avoided this except by refusing to undertake the ride. I suggest, however, that in such cases discretion may be the better part of valour, and that it may be wiser to refrain from tempting Providence too much even at the cost of a certain amount of delay and inconvenience.

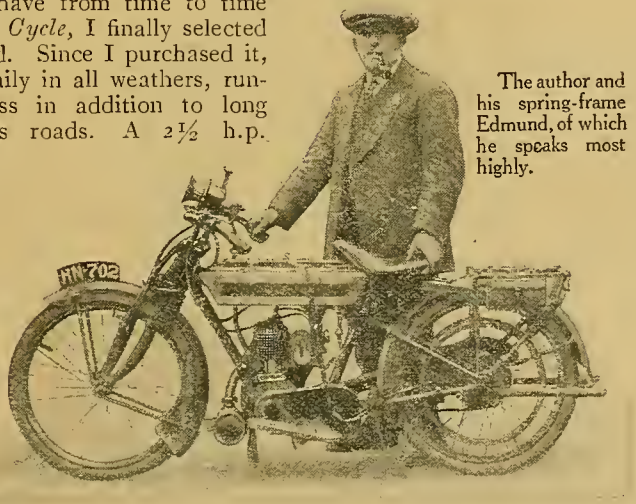
This is an extreme instance, but it is by no means uncommon to find that people whose teeth are bad, or who are subject to facial neuralgia, bring on an attack of the latter by riding insufficiently protected against too strong or too cold a wind. It is worth while taking a little trouble, perhaps even of risking a little ridicule, to provide adequate protection to the face. A simple, effective, easily procured, and by no means unsightly device, however, is a woollen helmet which fits closely over the head and neck, with just a space for eyes, nose, and mouth. With this there is no need for a hat and no fear of the head gear being blown away. It looks as comfortable as it feels, and costs only about a couple of shillings or half-a-crown.

One may admit, in conclusion, that motor cycling has certain risks and drawbacks. So has every other recreation. Yet not only are they of comparatively minor importance, but practically all of them may be overcome by the use of a little forethought and commonsense. No motorist who has once tasted of the joys of the open road would ever willingly give them up, even were the drawbacks much more serious than they are. But it is surely wise to minimise even slight disadvantages where this is both possible and easy. That these few simple hints may help someone to do this is my excuse for having set them down.

SPRING FRAME EXPERIENCE.

A Reader's Experiences with the Edmund Spring-frame Lightweight.

IN view of the enormous interest the springing of motor cycles has created, and the importance the question has undoubtedly assumed, it may be of benefit to potential purchasers of motor cycles to hear of the experience of one who appreciates comfort when riding. Having studied the various and numerous types of spring frames that have from time to time been illustrated in *The Motor Cycle*, I finally selected as my solo mount the Edmund. Since I purchased it, the machine has been used daily in all weathers, running to and from my business in addition to long country rides over atrocious roads. A 2½ h.p. J.A.P. engine is fitted, together with Enfield two-speed gear and Druid Mark II. forks.



The author and his spring-frame Edmund, of which he speaks most highly.

At first I was doubtful if this machine would safely carry my weight (*i.e.*, 14 stone), as it seemed so springy, but the very first ride dissipated all doubts. In a few minutes I adjusted the springs to suit my weight, and tackled some pot-holey roads. The result was a revelation to me: the spring frame never "bottomed," and there was no rebound. The sensation is simply one of floating. I might remark that the footboards are sprung in conjunction with the saddle, a refinement most acceptable.

As the frame construction does not allow of any lateral saddle play, the tyres cling like limpets to a greasy road, which engenders considerable extra confidence in a timid rider; in fact, any rider.

The back mudguard would be better fitted with a valance, on the lines of the Enfield, and the back brake should, in my opinion, be controlled through a Bowden cable to the footboard. My motoring experiences have extended uninterruptedly over about fifteen years, and as a private owner I have had several cars and more than a score of motor cycles of various types, including about ten sidecars, but have never previously written my experiences of any machine. In the present case I could not resist, as I desire others to realise the great difference between sprung and unsprung motor cycle frames. I am fortunate in having two new machines each season, a solo mount and a combination; the 2½ h.p. Edmund and the 6 h.p. Enfield are my present mounts, and both are entirely satisfactory.

PERCY ROBERTS.

MILITARY NOTES.

"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS "TANKS."

AN OLD WAIL.

IN sending us from France the photograph reproduced on this page of D.R.'s of the A.S.C., M.T., one of the trio says :

"The print portrays three motor cyclists in our scena, 'Don't motor for pleasure—We don't!' Our earnest hope is that your influence will prevent motor cycles being sent out with ½in. wheel-mudguard clearance, footrests in front of the crank case, and similar absurdities."

"Don't motor for pleasure—we don't!" say the above trio in France.

MUD SUCH AS ENGLAND NEVER SEES.

IN an interesting communication Second Air Mechanic H. W. Mason, who is attached to the 18th K.B.S. of the Royal Flying Corps, reiterates the old complaint of inefficient mudguarding. He says : "I thought motor cycling was bad enough last year, but on present surfaces it is fiendish. I was out one night recently, and had to empty the mudguards three times in about two hundred yards, taking the front wheel out each time to get the mud out properly. Another time I had to leave the front mudguard on the road, as it was hopeless trying to move with it on. I was just about fed up, so I reported it to the transport officer, who agreed that I could improvise a canvas shield for the front, and utilise part of a petrol can for the rear guard, as will be seen by the photograph. I have found with my experience that the secret of strenuous riding is bracing yourself up with a belt as tightly as possible. Before using one I experienced great discomfort in long distance riding on bad roads, but now I feel no ill-effects, whatever the state of the road."

THE "TANKS" ON THE SCREEN.

WHEN the "Tanks" first appeared on the screen last week they were greeted with the greatest enthusiasm. Long ago they seized the popular imagination. Photographs of them have appeared, but the general public have but little idea of the surroundings and methods of this type of attack. The *Times* said: "The only criticism to be heard of the pictures was that there was not more of the Tanks. One saw them preparing for the fray, lumbering into action with a majestic roll, and emerging from the ordeal of battle followed by crowds of cheering soldiers. The man who at the Scala expressed his disappointment that he had not seen a Tank climb a tree only voiced in exaggerated form the wish of many to see still more of these uncanny monsters."

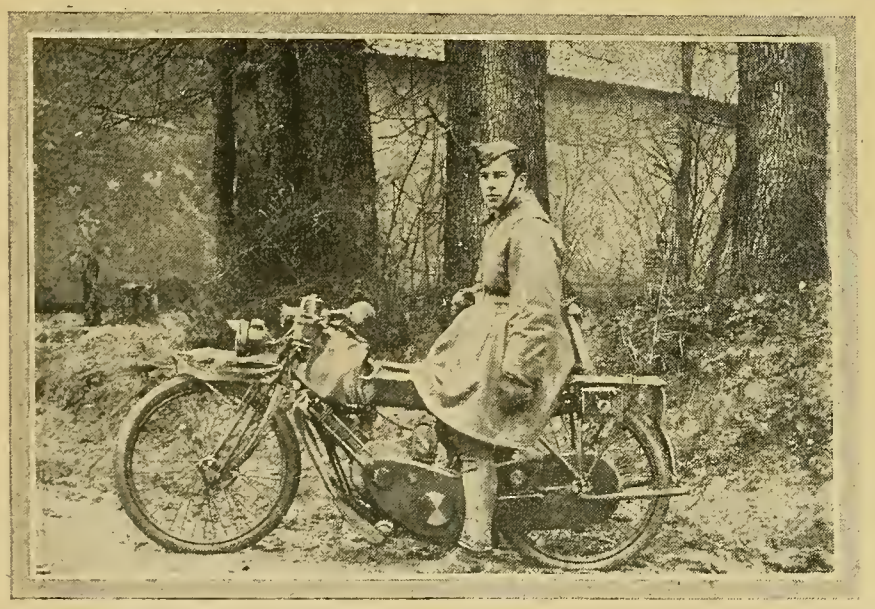
MENTIONED IN DESPATCHES.

AMONG the officers mentioned by Field Marshal Sir Douglas Haig in his latest despatch appears the name of Lt.-Col. J. J. Shannessy, the managing director of the Midland Rubber Co., of Birmingham, who is at the present time home on sick leave.

ARMOURED CARS IN GERMAN EAST.

AT different times we have referred to the exploits of the armoured motor cars in German East Africa. These cars are attached to light armoured motor batteries, the *personnel* of which was recruited by the Editor of this journal. A picture of a complete battery occupied the double centre page of our issue of February 24th last. Attached to the cars are over a score of motor cyclist mounted infantry, who act as scouts. A number of well-known motor cyclists are acting in conjunction with these batteries in G.E.A., among them being Sergt. Southcomb May, Dvr. W. Miles-Thomas, and Sergt. H. S. Bilbe. (The last named, we are glad to hear, is rapidly recovering from a severe attack of dysentery.) This is what Reuter says of the latest action of one of these batteries :

"Light armoured motors came to close quarters with the enemy on January 3rd. Their armour was plastered with bullets, the machines coming under a heavy Maxim fire. They did great execution, but were eventually forced to retire owing to a wrecked radiator and boiling tanks. They had, however, silenced the enemy's fire, and sustained no casualties among their crews."



Makeshift mudshields improvised by 2nd A.M. H. W. Mason, R.F.C The rear guard is made from part of a petrol tin. (See paragraph.)

Bearing Pressures and Length of Stroke.*

The Original Writer's Rejoinder to Mr. J. L. Norton.

IN answering Mr. Norton's article in *The Motor Cycle* of January 11th I will use *actual* figures of the *actual* engines under discussion, for such an article cannot be answered in mere words. Firstly, I will confine myself to pointing out some of the more obvious errors. Mr. Norton says :

1. "Piston weight increases more rapidly than in direct proportion to an increase in size." This is surely wrong, because the area of a circle increases as the *square* of the radius, and its diameter increases directly as the radius. In two pistons, one of, say, 2in. diameter, the other of 4in. diameter, the latter would be four times the area, but would roughly have only twice the amount of metal in it. In the case of an 88 and an 82 mm. piston the difference is very small. Mr. Norton's first statement, then, is quite wrong.

2. "There being nothing to prevent both engines being balanced to the same degree of accuracy." In this I beg to differ. Mr. Norton has forgotten that the inertia stresses are greater in a long-stroke engine, owing to the length of its stroke, and are greater during the first half of the stroke.

Explosion Pressures.

3. I still adhere to my original statement of bearing sizes. The actual fact that, in spite of taking a piece out of the flywheel rim, the bearing of the Norton engine is *still much smaller* than the other, remains to *prove* my statement. I have shown, in my letter of December 7th, that the pressure on the big end bearing (neglecting inertia pressures) is 268 lb. per square inch, and that means practically 30% *greater* on the long-stroke than on the other engine.

4. Gudgeon pin bearing pressure on the explosion stroke (counting explosion pressures only) is 140 lb. per square inch, *i.e.*, 6.5% greater on the short stroke. Compare this with 30% greater on the long-stroke crank pin, and Mr. Norton's statement with regard to rebushing the gudgeon pin of the short stroke, owing to greater pressure, etc. I have yet to add inertia pressures, which practically equalise matters.

5. In quoting Mr. Norton with regard to putting a recess in the flywheel rim being a "slight advantage to balancing," I presume Mr. Norton means he can have a slightly lighter balance weight, otherwise the recess is a detriment to balance.

6. If in his instructive little drawings, Nos. 2 and 3, Mr. Norton had shown the piston in its proper place, viz., on the flywheel centre line, and noted the angularity of the rod in both cases, I think the drawings would have been even more useful than at present. I will, however, give the actual load on these bearings later.

Lubrication.

7. To give Mr. Norton his due, his lubrication ideas are really much in advance of anything I have previously seen. To suggest, in the engines under consideration, that, because the big end of the shorter stroke engine revolves in a radius $\frac{7}{16}$in. less than the long stroke, the latter is in the best possible position for lubrication, can only be characterised as prejudice. I venture to think few people will be misled by it.

8. Mr. Norton states that there is a return "for piston pressure due to the increased angularity of the long-stroke connecting rod." Why, if this effort is returned, does any engineer who knows his business specify as long a connecting rod as he can obtain for his engine? It is perfectly clear, as the rod becomes shorter and shorter, the less power is exerted on the crank pin and the more is wasted in pressure on the cylinder walls. The actual pressures are touched upon later.

9. Mr. Norton is very brief on the subject of centrifugal pressures. He wants to claim two conflicting advantages for the long stroke. He wants it run at a lower speed of revolution, and yet to keep its advantage of pulling at very low speeds. This cannot be done, as it means, in the first case, a higher gear; or, in the second, the same gear as the shorter stroke engine. The revolutions at which I proposed running our engines were 1,500 r.p.m., corresponding to a road speed of around 21 m.p.h. This is an average speed, and, it is safe to say, as often exceeded as not. Therefore, as in running the two machines I considered I used practically the same gear ratios, I am still going to adhere to this speed. The standard 4 h.p. Norton is not supplied, when sold, with a higher gear than is the other and smaller engine, therefore I am justified in my rating.

Multi-cylinder Engines not under Discussion.

The concluding quotation from Mr. Lanchester is really a weakness. It makes one think that Mr. Norton is trying to apply the idea of a multi-cylinder engine, such as Mr. Lanchester referred to (and on which subject I may say there are different opinions), to the case of a single-cylinder engine, which, as Mr. Norton is apparently unaware, stands in a class by itself.

My calculations are appended, and all I have to say, now that Mr. Norton has forced the matter is : How does the long stroke engine compare with the medium stroke?

	Long Stroke.	Medium Stroke.
Revolutions per minute ..	1,500	1,500
Weight of reciprocating parts in lb.	1.5	1.625
Stroke in feet	.393	.314
Area of piston head	8.18 sq.in.	9.42 sq.in.
Explosion pressure (250 lb. sq. in.)	2,046 lb.	2,356 lb.
Force necessary to reverse piston at end of each stroke (neglecting angularity of connecting rod)	225 lb.	196 lb.
Increase of force due to angularity of connecting rod (top half of stroke)	65 lb.	45 lb.
Total force acting on bearings	2,336 lb.	2,597 lb.
Pressure per sq. in. on small end	2,312 lb.	2,425 lb.
Pressure per sq. in. on big end	1,946 lb.	1,426 lb.

As concerns, then, the above, the bearing pressure on the gudgeon pin bearing, which, we must remember, merely oscillates, is nearly 5% greater on the short-stroke engine, taking Mr. Norton's conditions. It has, however, to withstand this pressure through a distance of, roughly, 25% less than the long-stroke engine, so, we may assume, will have a fair margin of life over that of the long-stroke.

In the case of the big end the pressure is *35% less* on the medium-stroke engine. There is only one conclusion to be drawn from this.

Balancing a Single-cylinder.

As regards balance, the secondary unbalanced forces on the long-stroke engine are nearly 50% greater, as shown during the first part of a stroke of the piston. Taking the long-stroke engine force of 225 lb., the force will vary plus and minus 65 lb. at each half of the stroke. This force can only be balanced by another connecting rod, which would have to work in direct opposition, as in the flat twin engine. Mr. Norton will doubtless, then, realise what the balancing of a single-cylinder engine involves, and why I stated that the long-stroke engine can never equal the medium-stroke in balance. As far as comparing the pressure of the piston during the explosion stroke on the cylinder walls, the figures I give may be interesting, as they are correct. On the long-stroke engine, the actual pressure will be a matter of *637* lb. total pressure.

On the shorter-stroke engine this figure is *577* lb. In addition to this the *area* of the *long-stroke* piston is considerably *less* than the other. Also, as far as the consumption of power goes, this is occurring for a 25% greater distance than on the medium-stroke engine. A.A.S.

*We think it well to point out that "A.A.S." is not comparing engines of identical capacity.—ED.

"Motor Cycle" Index Ready.

Any reader desirous of the index to *The Motor Cycle* from July to December, 1916, may have a copy posted to him for threepence.

A Motor Cycle in a Raffle.

The Russian-American Relief Association recently organised a large bazaar in New York, and a good sum was raised by the raffling of a fully equipped Harley-Davidson motor cycle, presented to the Association by the H.D. Co.

British-made Indians?

In select company recently, Mr. W. H. Wells, London manager of the Hendee Manufacturing Co., made more than a hint that after the war a factory would be erected in this country for the manufacture of Indian motor cycles.

Good-bye, Bosch!

Over 165,000 magnetos have been made in Britain for war purposes, and to-day the war is being conducted on British-made magnetos. After the war there will be no further need to buy enemy or other foreign magnetos.

Recruits for the Tanks.

"The famous Tanks are very largely manned by motor cyclists, the section being chiefly recruited by the leading motor cycle journal in England," says our contemporary *Canadian Motor Cycle*. It is customary to surround the motor cyclist in the firing line with a certain amount of dashing glory, but now he is almost eclipsed by the gallant crews of the slow-moving, trench-crushing Tanks. Certainly the motor cyclists in the Tanks see more genuine fighting than the motor cyclists awheel.

Alphabetical Disorder.

In an article entitled "Flat Twins Popular across the Water," reproduced with illustrations lock, stock, and barrel from *The Motor Cycle*, an American contemporary, after stating that "we will now deal briefly with some of the more popular flat twins in alphabetical order," heads the *alphabetical* list with Indian, the A.B.C., Bradbury, Brough, etc., following after. This is evidently on the grounds that A(merica) heads the list, B(ritain) coming next; but there is obviously no hiding a candle under a bushel in America.

The Outlook.

Last week's news, summed up in a nutshell, was a possible reduction in the petrol allowance, and an increase in the cost of tyres.

Miniature Motor Cycles.

The power-driven skicycle, similar to the American Autoped, cannot claim to be original in design. The first machine of the type was the Max, exhibited at the Stanley Show in 1905. Many will recall this miniature, but few know that Messrs. Douglas Bros., Bristol, made it to the order of the patentees. It had a J.A.P. engine. Later the "Motor Frip" made its appearance. Mrs. Kent was responsible for the Motor Frip, which she intended for ladies' shopping expeditions. This machine had three wheels, and was propelled by a 1½ h.p. Moto-Rêve engine.

SPECIAL FEATURES:

THE HYGIENE OF MOTOR CYCLING.
BEARING PRESSURE AND LENGTH OF STROKE.
STANDING ROOM ONLY.

British Magnetos.

Magneto making, which till 1914 was almost non-existent in this country, has now been scheduled as a "key" industry.

Involuntary Use of Benzole.

A correspondent informs us that, petrol being asked for by a car owner at a large garage in a fashionable South Coast watering-place, benzole was poured into the tank from sealed petrol tins! Such an experience is not so much to be dreaded as the substitution of paraffin mixtures for petrol, nor is it so likely to occur.

G. W. Wilkins, of Sheffield, in the saddle of a 4 h.p. Norton, and his friend in the sidecar, A. Blake, will be recalled by Midlanders as well-known competition men. Wilkins rode a two-stroke Levis in the last Six Days' Trials, and won a bronze medal in the lightweight class.

Starting on Acetylene.

We have received a letter from an experienced chemist, too late for inclusion in this issue, warning motor cyclists against the use of acetylene in their engines. This, he says, is very dangerous, and those who escape accident while using it do so simply by good luck.

Shell Oil Production.

The Shell Transport and Trading Co. announces that the oil products owned and controlled by the associated companies amounted during the past year to 5,155,000 tons, against 4,367,384 tons in 1915 and 4,786,000 tons in 1914. The output would have been larger had it not been for the conditions prevailing in Mexico and the impossibility of obtaining steamers for shipments of oil from that country.

A Double-barrelled Event.

An extremely strenuous endurance test between San Francisco and Los Angeles started on December 14th appears to have been a double-barrelled event, some of the competitors starting from Los Angeles and the remainder from San Francisco. A distance of 870 miles was covered, and the following machines finished with perfect scores: Five Harley-Davidsons, three Indians, three Excelsiors, and two Hendersons. Many competitors succumbed to the great difficulties of the trial.

Lamp Makers Please Note!

On finding that the new Lighting Order distinctly specifies that the lamps of a sidecar outfit must show the extreme width of the vehicle, a reader, while gloomily contemplating the design of a front fork bracket by which the lamp could be mounted clear of the bars, decided to write the Home Office. Great was his relief on hearing from the Secretary of State to the effect that "the Order was deemed to be complied with if the lamp were attached to the front pillar in the ordinary way."

Mounted Police.

The Sydney motor cycle police are mounted chiefly on British-made machines, including Douglas, A.J.S., B.S.A., James, Speedwell, and Rover. "Some exciting dust-ups are being eagerly awaited," remarks the motor cycling journal of New Zealand.

M.C.C. Meeting.

The ordinary general meeting of the members of the Motor Cycling Club, Ltd., will be held at the Monico, Piccadilly Circus, London, W., on Wednesday next, the 31st inst., at 6.30 p.m., to receive the annual report and statement of accounts, and to transact the general business of the company.

War Loan Subscriptions.

The B.S.A. and Daimler Co. have subscribed £500,000 to the War Loan, £430,000 of which is new money. The Dunlop Rubber Co. have applied for a quarter of a million, and the stock now applied for by the Automobile Association brings their total investments up to £77,000.

Aeroplane Body for Runabouts.

The average motor cyclist is keenly interested in aviation, and sporting men who use sidecars and runabouts favour a streamline body in preference to any other. In our sister journal *The Light Car*, published yesterday (Wednesday), there is a striking illustration of a typical aeroplane fuselage mounted on a light car chassis. Suggestions accompany the illustration as to what would happen if the "joy stick" were pulled.

Motor Cycle Thief Busy.

We are advised by Gnr. C. E. Fowke, of the Heavy Section, Machine Gun Corps, stationed at a camp near Wareham, Dorset, that he has had his 1914 pattern 3½ h.p. Triumph stolen. This model has a three-speed hub gear, and Gnr. Fowke's machine had T.T. handlebars, whilst the bottom fin of the radiator between the valves was broken off.

The National War Funds.

At the week-end the principal war funds stood as follow:

The Prince of Wales's Fund (distributed £3,529,719)	£6,025,027	0	0
British Red Cross Fund	6,002,820	0	0
Tobacco Fund	124,096	0	0

Avoiding Tail Lamp Troubles.

A correspondent writes us that after months of trouble with a choked tail light burner he has discovered a trick which completely overcomes the difficulty. On putting the machine in at night he turns off the water and quickly pinches the tube under the head light. This causes the whole pressure of gas from the generator to blow through the tail lamp, which, after about fifteen seconds, is extinguished. The excessive pressure of gas thoroughly scavenges the small burner, though, of course, the hint only applies in cases when both lamps are fed from the same generator.

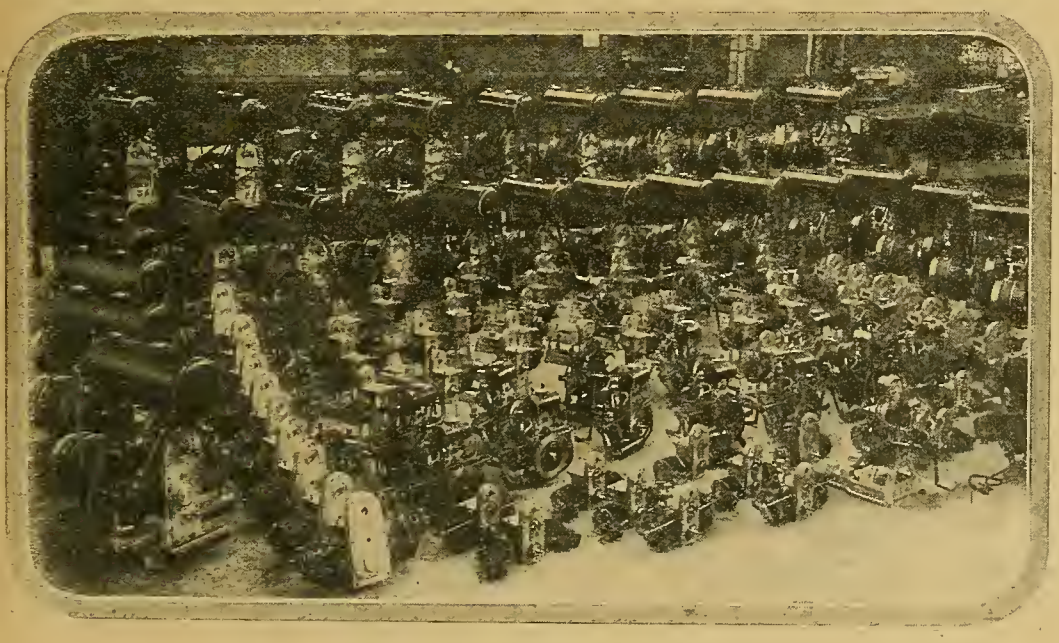
American Adoption of Term "Flat Twin."

Mr. John M. Taylor, of the Hendee Co., dislikes the term "flat twin" so much that he has gone to the trouble of denying its American origin in a letter issued to all the technical journals. "We have undoubtedly played a great many tricks with the English language," writes Mr. Taylor, "but we have not perpetrated 'flat twin.'"

No need for this denial, since *The Motor Cycle* takes full responsibility! But Mr. Taylor stoutly shoulders the even greater responsibility of speaking for the American nation by stating that the term would never find favour in the States! We note that the two leading American motor cycling journals and also the Canadian journal have already cottoned on to the term, which promises to become universal!

An Irish Opinion.

The *Irish Cyclist and Motor Cyclist*, referring to this term, says: "It is expressive, and, though America may not like it, it will stick."



FLAT TWINS FOR WAR PURPOSES

Because four firms supply practically the whole of the Government requirements in respect of motor cycles it must not be supposed that other motor cycle firms are not producing engines for war work. Our picture shows a batch of 120 A.B.C. flat twin engines nearing completion, all constructed to Government orders and intended for various power unit purposes. The engines range in capacity from 225 c.c. to quite large dimensions.

Necessary and Unnecessary Kit.

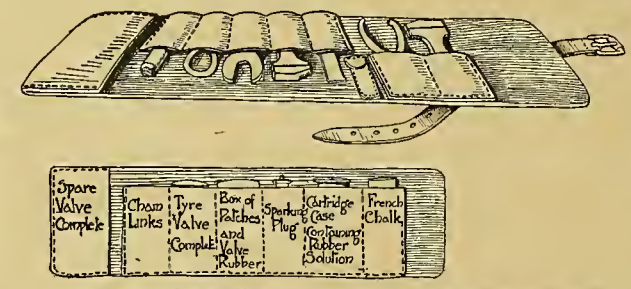
A FEW HINTS ON WHAT TO CARRY AND HOW TO CARRY IT.

MANY riders, on parting with an old machine, bundle into the kit bags a surprising assortment of cast-off kit, and the next man, telling himself that these belong to the machine, and should therefore remain where they are, conscientiously carries them about with him, much to the detriment of the kit roll and the saddle bags. On purchasing a second-hand machine, one's first act, after sounding the bearings, transmission, etc., should be to subject the kit roll to a searching examination. It is usually a simple matter to sort the tares from the grain, and the sundry tools with rounded corners and battered edges should be placed at the bottom of a deep hole in the back garden and carefully covered over.

A question one might seriously ask the novice, mounted on a second-hand machine, is—Are you carrying unnecessary kit? If so, drop it. Do not imagine it will ever be of use to you. It won't.

Necessary Kit.

With a new machine one or two set spanners are supplied, which should always be carried. In addition to the valve cap spanner, there are probably three smaller spanners belonging to the machine, and, as regards other tools, one's requirements are really quite modest. As Jerome put it, the question to be decided is, "What can we do without?"—not "What can we do with?"



A neat way of arranging the tool kit. A little method and care in this direction will save many shillings, and also much loss of temper.

The list of kit adequate for ordinary touring may be set down as follows:

Special keys belonging to machine.
Large shifting spanner.
Small ditto.
B.S.A. key.
Tyre levers.
Screwdriver.
Easy working pair of pliers.
Magneto spanner.
Belt punch or chain rivet extractor.

Spares.

As regards spares, there is no wisdom in stinting oneself. Carry always a spare tyre valve complete, and also a large-sized patch, so that, should the valve tear out of the tube, a complete repair can be made. If space permit, carry a tin of rubber solution rather than a tube. The following articles may be set down as the necessary contents of the spares bag, which occupies the opposite side of the carrier from the kit bag:

Tyre valve complete.
Patches, valve rubber, French chalk.
Rubber solution and emery cloth.
Tyre gaiter.
Engine valve complete.
Sparking plug (carefully padded).
Spare chain links or belt fastener.
Small assortment of nuts, bolts, and screws.
Roll of insulation tape.
Length of copper wire.

The Spare Tube—What to do with it.

A spare tube is, of course, advisable for serious touring, and may save trouble and discomfort at any time. To carry it without damage requires care.

Draw all the air out of the tube, then refix the valve and roll the tube neatly, wrapping it first in a damp, clean cloth, liberally sprinkled with French chalk, and secondly in a strip of American cloth, making the parcel as neat and firm as possible. The packet can then be fixed under the lamp bracket or in some other convenient position where it will be secure from oil. Do not carry the spare tube in one of the carrier bags or even in a special tube carrier, unless it is very carefully packed. I can suggest no better way of carrying the tube than that of making a special bundle of it, securely tied where it rides without excessive jolting. Naturally, the handle-bar is the best place.

A Home-made Tool Roll.

Spares and tools are really worth taking care of, and since their preservation is a matter of thought, rather than of trouble, the foregoing hints may be of some little value. The secret lies in carrying as little as wisdom permits, and in seeing that the few tools and spares one *does* carry are firmly packed in the panniers, and are not left to jolt holes in themselves and everything else with which they come in contact.

I have met the man who carries only a huge shifting spanner loosely in the pannier, and I suppose we are all familiar with the sportsman who opens his tool roll and stares in blank bewilderment at the array, having no notion what half the tools are for. Carry only necessities, and pack them well.

Necessary and Unnecessary Kit.—

As a rule it undoubtedly pays to buy the ready-made article rather than waste time and material by attempting to carry one's own brilliant notions into practice, but such an article as a leather kit roll can be very advantageously made at home. I still have in daily use a kit roll which I made five years ago, its long life being due to the secure manner in which it holds the tools, and to the good, tough material of which it is made, and I prefer the home-made tool roll to the bought article for the following reasons: (1.) By judicious arrangement the heavy tools one always carries can be made to lie flat in the roll, so that it straps up compactly and snugly (in a bought roll one has to place the big tools where they will go, rather than where they fit in best with one another). (2.) One can select a really tough leather and employ really strong stitching. (3.) The home-made article costs about one quarter of the bought article, and if properly packed in the pannier it lasts indefinitely.

How to Make the Roll.

Purchase a piece of tough, fairly stiff leather of the desired length and width, not stinting oneself as regards length, for even should it prove necessary to cut it down, a few bits of leather are always useful.

In addition to this stiff piece purchase a lighter piece (preferably thin pigskin) of the same length as the roll, and about 3in. in width. Now start off by turning inwards the end of the roll, so as to form a fairly deep pocket for the two or three small spanners belonging to the machine, as shown in sketch. Place the spanners in the pocket, then lay the remaining tools flat on the roll—the small ones at the pocket end, and the large ones at the opposite end—and roll up the strip, this being to find out the positions the tools should finally occupy for compactness and snug fitting. A surprising amount of kit can be rolled into very small space if properly arranged.

Having now found the best positions for the tools, the next thing is to arrange the pockets. The 3in. strip of thin leather is cut in half, and, with the tools still in place on the roll, the thin strip is loosely tacked in position over the tools—brass paper pins coming in very handy at this point.

The positions of the pockets now being fixed, the stitching can be left to the local cobbler, but it is more satisfactory to finish the job oneself, so obtain from the cobbler a few yards of wax end, taking care to stitch the corners and edges very strongly. This done, the kit is rolled and the strap fixed. Cheap straps are of no use for kit rolls. Buy a good pigskin strap, and it will comfortably last out the roll.

It is a good plan, while in the mood, to make a juvenile roll on the same lines for carrying spares and tyre repair outfit, this being kept in the second pannier, where only light stuff is stored. H.M.B.

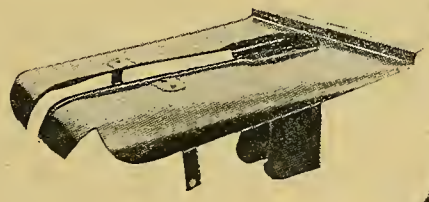
OFFICIAL RECOGNITION FOR MOTOR VOLUNTEERS.

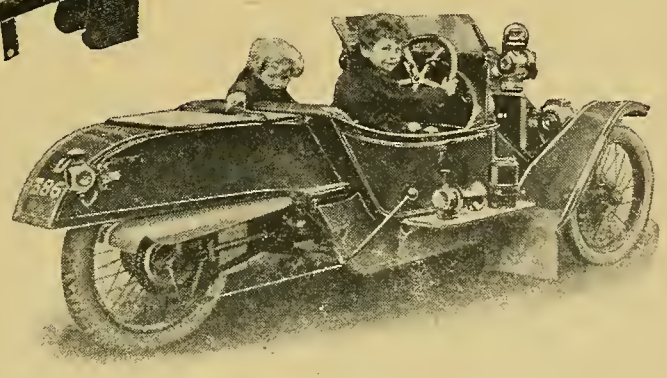
THE Motor Cycle has made it plain in recent articles that the question of the recognition of Motor Volunteers was only a matter of time. We are now in a position to state that the Government has decided to recognise existing motor organisations and organisations by counties, whether light or heavy squadrons. If and when the Field-Marshal commanding the Home Forces considers it necessary for training, petrol will be allowed. The primary duty of the Motor Volunteers is to provide the Volunteer Infantry with transport. A light squadron consists of fifty-six cars and twenty motor cycles. A heavy squadron twenty-four lorries, eight cars, and twelve motor cycles.

A TRANSMISSION GUARD.

A REFINEMENT WHICH SHOULD APPEAL TO MORGAN OWNERS.

A MUDGUARD specially adaptable to Morgan Runabouts, and which has been registered by Mr. Arthur A. Jaffa, 127, Vauxhall Road, Liverpool, is shown in the accompanying illustrations. It will be seen that the guard is fitted directly above the chains, so performing a dual purpose by preventing any mud from the upper portion of the machine falling on to the chain drive to the detriment of the wearing qualities of the latter, and at the same time preventing the chains from slinging liquid mud over the machine. The excellent qualities of the Morgan runabout are well known, but in wet weather, when there is a considerable amount of surface water and liquid mud, the tail portion of the machine often becomes bespattered with dirt. Owners who may have experienced this trouble will be glad to know that Mr. Jaffa intends placing the guard on the market. Its design, as well as the special attachments, are shown in the upper illustration. The downward extension envelops the tyre and acts as an extra screen for the gear box and the change-speed operating mechanism.





An effective transmission guard designed specially for Morgan Runabouts. One of the guards is shown fitted to the Grand Prix Morgan illustrated

NO PETROL FOR NEW MOTORISTS.

THE Petrol Committee announced on Monday afternoon last that, in view of the urgent necessity which has now arisen for further limitation of the consumption of motor spirit, it will not be prepared to issue licences on any applications received after yesterday (Wednesday), the 24th inst., unless such applications are for the renewal of licences which have expired in the ordinary course. The committee cannot undertake, however, that it will be able to issue renewals on all applications received from holders of motor spirit licences, and in any case it may be necessary to reduce the quantity of motor spirit at present allowed. Every effort will be made to avoid disturbance of the existing arrangements under which the committee receives applications.

MANUFACTURERS AND NATIONAL SERVICE.

WE learn that the deputation of manufacturers appointed by the Motor Cycle Manufacturers' Union has not yet seen Mr. Neville Chamberlain, the Director General of National Service, nor had an appointment been made at the beginning of the week.

Importance of Overseas Trade.

At least one important firm of motor cycle manufacturers has been granted a permit to continue the manufacture of motor cycles, with the stipulation that they are for export only. The notice is subject to one month's cancellation. The efforts of other firms to obtain a permit to continue the manufacture of motor cycles, even on the understanding that their energies would be devoted entirely to Overseas trade, have not been successful, but many are still hopeful that the authorities will grant permits before the date of the expiration of the old licences, viz., February 15th.

FARM TRACTOR DRIVERS WANTED.

WE have been asked to secure immediately twelve men for driving motor tractors and ploughs to be engaged on agricultural work of a very urgent nature in Scotland. Experienced drivers are essential. These men are badly wanted, and we might add that every day saved in placing them at work is of great value from a food supply point of view. Motor work on agriculture is likely to become a very important sphere of duty for motorists in the future, and the experience to be gained by men who take up the above positions will be invaluable. We are confident that a sufficient number of offers of service from men (preferably over military age) well qualified for their duty will be forthcoming, and we have undertaken to test applicants where necessary, and place them at the disposal of the Government forthwith. All communications to be addressed by letter to Iliffe and Sons Ltd., 20, Tudor Street, E.C.; Coventry; or Century Buildings, 199, Deansgate, Manchester.

PATRIOTIC PROBLEMS.

MR. E. T. NORTH, at an address to the Sales Managers' Association, advocating the adoption of an official British national trade mark, stated that in 1913 British men and women spent 35s. on German productions to every 3s. 11d. the Germans spent on British productions. It is to be feared that motor cyclists contributed not a little to these results, but now that we have our huge magneto and accessory factories it will be a poor look-out for German goods after the war.

AN HOUR ON A FAMOUS ROAD.

THE Birmingham-Coventry road last week-end was lively with motor vehicles of all descriptions, in spite of its glassy surface. A sidecarist, evidently anticipating frame breakages, took to the pathway to avoid the hills and dales of the roadway. A few minutes afterwards a war lorry came racing along at a speed of at least thirty miles an hour, doing more damage to the surface than fifty cars could do in the time. After an interval a sidecar ambled along in a drunken fashion, with the lug of the eye bolt broken owing to the enormous pot-holes. The riders had come from Rochdale, and state that, if possible, the roads in that district are even worse than near Birmingham. It was interesting to observe the various solo riders on the icy surface. Some rode in serene confidence, most of these being, curiously enough, riders of single-cylinder machines; others pottered along in agony of suspense, inviting a skid by swinging their legs free of the footboards. Movement of the legs is very likely to upset the balance of a machine on a slippery surface.

TWO-STROKE ENGINES IN AMERICA.

IN America the motor boat is the forerunner of the railway—the forerunner of civilisation. Every city and mining camp, where water transportation is possible, has its fleet of gasoline launches, ranging from the racing mammoth to the converted canoe. Two-stroke engines are widely used, and small, light, two-stroke power units, suitable for the smallest of craft, have long enjoyed a tremendous market in the States. This fact makes it all the more curious that the American two-stroke motor cycle has taken so long to materialise.

"UNE SAUCISSE."

Captive "sausage" balloons are used extensively on both the French and British fronts. The Germans, of course, possess similar contrivances. It will be remembered that just before the great Somme offensive our airmen succeeded in bringing down practically all the enemy's captive balloons which hovered over that particular sector A despatch rider's machine is seen in the foreground. (*Vise par le Ministere de la Guerre.*)

A WAR FUND CARNIVAL.

The East London M.C.C. (South Africa) recently held a carnival in aid of a convalescent home. It will be seen by the photographs that many of the fancy dresses were most effective. The club has thirty-six members at the front in German East Africa and Europe. Weare indebted to the Vice-captain E.L.M.C.C. (W. E. Courtney) for the photographs.

AVERAGE PRICES.

WE give below the average prices of second-hand models offered for sale in *The Motor Cycle*. Where it is possible to obtain a sufficient number of each model the average for the past week is quoted, otherwise the last average is given, if within four weeks. Difficulty in obtaining a sufficient number of one particular model often arises, owing to the fact that many advertisers omit some of the most essential details.

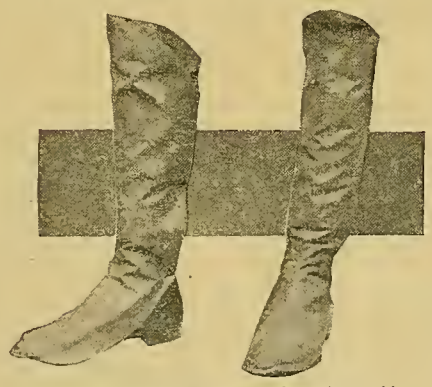
THE CYCLOSPAT LEGGING.

WE have received from Messrs. Brown Bros., Ltd., Great Eastern Street, London, E.C., a sample pair of their new Cyclospat leggings, which are designed chiefly to meet the demands of those who use their machines for short journeys, and who wish to protect not only their clothing but their boots from road splash. The leggings are quite suitable for serious touring, but they will appeal particularly to the man who uses his machine chiefly for short runs, which do not necessitate the donning of a whole suit, on account of their lightness and the ease with which they can be slipped on and off.

A distinctive feature in the Cyclospat legging, which we think might be more generally followed by overall manufacturers, is the toe-piece with leather sole,



The Cyclospat, a very handy and quickly adjusted overall or legging specially suitable for short and frequent journeys.

which fits over the toe of the rider's boot, thus preventing water from entering at the lace-holes, and also keeping the boot dry and clean. The nuisance of muddy boots is entirely eliminated by this simple extension—a point which will appeal strongly to business riders and doctors.

The Cyclospat leggings are made of durable waterproof material, and are attached by elastic bands and snap fasteners. Three sizes are supplied, the retail price being 4s. 6d. per pair.

ROTARY-ENGINED MOTOR CYCLES.

IT must not be supposed that a rotary engine is anything new on a motor cycle. Those older motor cyclists and people connected with the trade about twelve years ago will recall the Barry rotary-engined motor bicycle, which was produced at Barry (Cardiff), and exhibited first at the Stanley Show, Islington, in November, 1904. An improved design of the same engine was also exhibited outside one of the earliest Olympia shows. The engine was kept running almost continuously during show week, as was evident from the amount of oil which it had flung about. The original 1904 engine was a four-stroke, and had two opposed cylinders on one crank case, the opposite arms of the cross forming a gas chamber and a silencer respectively. Its weight was 15 lb., and the complete bicycle 70 lb. A later model was illustrated in *The Motor Cycle* of March 13th, 1905, wherein the engine was lower in the frame, and enclosed with a perforated cover instead of a plain one. For years the inventor bravely stuck to his task and eliminated many troubles which had manifested themselves, but of late years we have lost trace of the engine and its clever designer.

In submitting to the Editor articles, photographs, or drawings, contributors are asked to mention whether the illustrations are exclusive, and further to enclose a stamped addressed envelope for return of unaccepted contributions.

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

VAPORISATION AND VIBRATION.

Sir,—With reference to Mr. A. H. Burslem's vaporiser for heavy fuel, I suggest that the vibration of a motor cycle would upset the thermo-syphon action. The heat of the water, if boiling, which is not likely, would hardly be great enough to effect much of a change; and the design on page 38 does not show enough difference in the in and out tube levels to create the syphon action.

(Pte.) W. E. SLEIGHT.

LIGHTWEIGHT TRANSMISSION.

Sir,—*Re* your article in *The Motor Cycle* of January 18th, I have recently taken delivery of a 1917 Diamond-Jap motor cycle. This machine is fitted with Enfield two-speed gear and chain-cum-belt transmission, such as is specified as ideal by "H.M.B." From my experience, so far, it has proved to be the sweetest driven motor cycle I have ever sampled, not excepting all belt-driven two-strokes. The clutch action, as the writer states, is exceptionally useful for restarting on hills and for traffic work. R. HUMPHREYS.

BEARING PRESSURES.

Sir,—I have only just returned from France after coming in contact with a Hun infernal combustion engine, which has left me with a fractured thigh. I have been almost out of contact with the motoring world for a couple of years, and it is refreshing to find still the same old arguments of long v. short stroke engines. My experiences show that the long stroke is decidedly the cooler of the two, which is the chief thing in continuous running.

I consider, in my humble opinion, that the question of bearing pressures is largely a matter of leverage. Thus, the greater the distance between the axle and the big end the greater the strain on the side bearings.

The lever tendency on the upper part of the explosive stroke puts more strain on the axle bearings on the long stroke engines than on the short stroke as the distance or length of lever is greater, and at the same time the long lever gives more power to be transmitted to the road wheel. So the advantages are about equal in each case.

(Pte.) W. E. SLEIGHT.

WATER INJECTION IN A PETROL ENGINE.

Sir,—In the issue of January 11th some interesting points are raised with regard to the introduction of water into the cylinder of an internal combustion engine in an attempt to combine the use of steam and gas expansion.

Your correspondent "W.M." says, "Evidently there is a fly in the ointment," and then he cites two claims against water injection. The first objection he brings forward concerns the impurity of water. Surely "W.M." could use distilled water. If he objects to the bother of distilling the water there is still another method which he unwittingly suggests himself. Your correspondent informs us that when the water is changed into steam, the impurities are left behind in the cylinder. It would be a simple matter to have a small generator in the exhaust pipe and then lead the steam around the cylinder, between the fins, to some convenient place of admission.

To the best of my knowledge there is no sulphur in good motor spirits, but were this element present it would not be the cause of valve corrosion, as "W.M." suggests. Sulphur trioxide (*not* sulphur) when dissolved in water forms sulphuric acid ($H_2O + SO_3 = H_2SO_4$). A very small quantity of sulphurous acid would be formed, but this unstable acid has not the harmful effects of H_2SO_4. In time a little sulphuric acid would be formed—the reason cannot be given here—but the bad effects would be negligible. Thus "W.M.'s" second objection is dispelled.

If steam is subjected to a very high temperature it breaks up into its two constituents (oxygen and hydrogen). The oxygen would mix with the explosive "mixture," and so form a more violent detonation when ignited. The hydrogen would also burn, producing water which would change to steam, and then go through the same process as just described. Thus it will be seen that water will be produced in fairly large quantities. It is possible that the H_2SO_4 produced would unite with the water, generating great quantities of heat and forming hydrates of $H_2SO_4 \times H_2O$, which would pass out of the engine. Perhaps the excess of water and heat are points which are the real disadvantages of water injection. Much can be written on this subject and conflicting theories advanced, but "the proof of the pudding is in the eating." G.R.H.

Newcastle-on-Tyne.

DECARBONISING FLAT TWINS.

Sir,—In your issue of January 18th, in an article by Mr. Eric Williams, the writer states that "flat" twins in most cases have to have the whole engine taken out for decarbonisation, etc.

I think this is rather a sweeping statement, although I do not hold any particular brief for flat twins, in spite of the fact that I ride one, a 500 c.c. Brough, also a 3½ h.p. single o.h.v. Martin-Jap, in which case the crank case has to be dropped to remove the cylinder.

In the case of the Brough both cylinders can be removed for decarbonising, *without* moving the crank case, quite easily. The magneto can also be removed by loosening two nuts and the Bowden control; it then slides off intact. I have no connection with Messrs. Brough except that of a satisfied user, but think the statements above referred to rather unfair on the whole "breed" of flat twins—after all, not very numerous. C.L.C.

High Wycombe.

CAN THE LIGHT CAR EQUAL THIS?

Sir,—I was very pleased to see my Powerplus Indian double-seated turnout illustrated in *The Motor Cycle* of January 11th. I may say that I bought the turnout from Mr. Haste last year, and it was the identical photograph which you reproduce that he sent to me and which induced me to buy it.

But I certainly would not advise other motor cyclists to ride with this load unless they are absolutely certain of the couplings or attachments.

I pointed out to Mr. Haste at the time I bought the turnout how he was risking their lives, as there was not a sturdy coupling on the sidecar chassis; in fact, when I arrived at Chester (240 miles from Ipswich, I started at 7.30 a.m. and arrived at Chester 6.30 p.m.), there was not a single coupling tight. Luckily I did not have a passenger.

After I got it home I discarded all the original couplings and fitted a complete set of Mills-Fulford, which made a job of it. Now I can with safety take myself (over 12 stone), my wife (14 stone), and my two daughters (9 and 10 stone). I have taken my family from Chester to Llandudno and round the Marine Drive, and only had to use the low gear for the last bit.

I have fitted several little improvements, such as front guard side shields, rear guard ditto to keep the mud out of the springs, a pair of detachable leg shields, an extra handle-bar Bowden controlled air slide (which is top-hole both on pilot and main jets), and a sidecar light. J. HORSWILL.

THE FLAT TWIN AT THE BAR.

Sir,—I was pleased to see that Mr. Bradshaw replied to my letter, though I am sorry he does not reply fully owing, as he states, to my lack of technical information. I do not see what technical information Mr. Bradshaw requires; I like to leave out technicalities when in conversation or correspondence, because I have found that such a course generally is more desired by the motoring public, who are not all designers or engineers, and I have not found it necessary to impress one's technical knowledge upon everyone.

With regard again to the "hot side" and "hot top" controversy, I, like Mr. Bradshaw, will also leave it to the general motor cycling public to judge whether they would rather have cylinders cooled with the oil and the piston in addition to the radiators provided than have them not cooled at all and then experience pre-ignition and burnt up plugs.

With regard to the claim of Mr. Bradshaw that the A.B.C. aims at improved cooling, smoothness, capacity for continuous heavy duty, and correct and regular oiling, I will reply to these in their order.

Cooling.—From what I can gather the A.B.C. has nothing exceptional in this respect; in fact, the plugs show that it is rather hot on the top, and the fact of steel being used for cylinders, and the amount of experimenting and the change of designs which have been necessary to obtain this cooling, rather leads one to believe that it is not all that could be desired in this respect, although its designer may think so. I see nothing the matter with the cooling of the "Douglas," which has cast iron cylinders and side-by-side valves.

Vibration.—On this subject the "Douglas" and other horizontal twins with which I have had experience are as equally vibrationless as the A.B.C. (I mean by this it is not necessary to have a horizontal twin with steel cylinders, and incidentally a lot of correspondence about rude shocks, and pitiable sketches, hot sides, etc., to have a good engine). This is really the only reason why I "butted in" on this subject.

Exceptionally Long Life.—It is impossible to tell whether an engine has exceptionally long life until there are many on the road in the hands of the general public pulling sidecars. An engine which has exceptionally long life must be made of exceptionally fine materials and be exceptionally machined with no errors in the design. If these qualities are embodied in it, it cannot help giving long life. The same remarks apply to Mr. Bradshaw's claim for "correct and regular oiling."

Perfect Smoothness.—I think the M.A.G. engine excels in this respect, and will hold its own against any engine in the world, but it is not horizontal or flat.

Capacity for Continuous Heavy Duty.—The same remarks as above apply here.

Gear Box.—I see nothing extraordinary in an engine taking four speeds—any engine will, of course, but one prefers an engine that will do most work on one gear.

Cast Iron, etc.—I see that Mr. Bradshaw has not had time to go into the matter of mangles, etc. I should have thought that he would have investigated the excellent qualities of the best cast iron, such as is used on several air-cooled engines of high-class manufacture. The M.A.G. engine designer has found cast iron better than steel, and Mr. Bradshaw may be quite sure he would not use cast iron for his racing engines if steel were better. He once made them of steel until his experience taught him that cast iron could be obtained which was far better for wear, cooling, and absence of warp.

I was very happy to see that "A.A.S." upholds my remarks of December 14th. The design of overhead valves which he shows is somewhat similar to the M.A.G. racing engine, and also to most of the racing automobile engines, as well as, as "A.A.S." points out, the aero engines. I should think that if they were satisfactory on aero engines there is not much the matter with the system.

Some quite useful information has been given on the subject by Capt. Lindsay in your issue of January 11th, and as this gentleman has very great experience his remarks about overheated spark plugs and condensation in the inlet pipe in connection with flat twins are right to the point and absolutely correct. Capt. Lindsay states he has had as much trouble out of a horizontal twin in a month as he gets out of a single in a year.

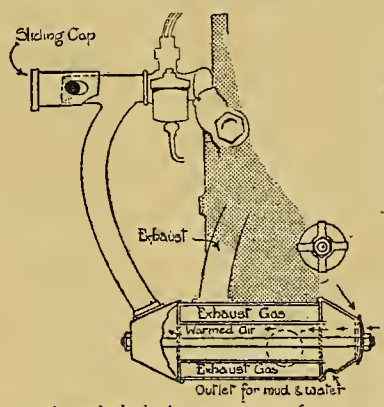
I was sorry to note that Mr. E. J. L. Strong read my letter in the light that he has, but I beg to assure him he is quite in error. I am pleased, however, that he was amused; I wish I could be amused during these times. As regards his friends, well it is one's duty at Christmas time to amuse people, especially the very young.

I have seen a letter from a Mr. Alf. Wray which is most amusing. He tells us, amongst other funny things, that the engine in question "is better designed than anything yet manufactured in the motor cycle world." So now we know, and there is no need to argue further on the subject—it is settled; but before concluding I would like to make one little remark. Mr. Wray tells us he was in the 1913 Tourist Trophy using an A.B.C. engine, but he does not tell us where he finished and why; he may have been amongst the also rans, but I didn't wait to see them come in. He also mentions he was in the practice for the 1914 race. Is that as far as he got in that year? Perhaps this is why he did not find spark plug trouble, cylinder warp, etc.

OSBORNE DE LISSA.

WARMING THE AIR.

Sir,—Perhaps this will be of use to a few Douglas riders troubled with freezing carburetters and indifferent fuels. It acts quite well, for the back of the carburetter is quite warm, even in the coldest weather. In fact, I have had to introduce cool air, as the too hot air made a difference of fifteen miles per hour on its maximum speed. The arrangement in regard to the silencer is to facilitate its coming apart, and also to prevent mud and rain from choking the air pipe.



A reader's device to prevent a frozen carburetter, and an aid to the vaporisation of heavy fuels.

The whole arrangement is fixed to the machine by the bolt passing through the silencer, and the tube nearest to the carburetter is loose and may perhaps slip off when a skid occurs.

The ordinary Amac carburetter very often collects rain around the sprayer; this does not happen now, thank goodness. Of course, it is not good practice to use hot air, but by the use of the sliding cap the air can be cooled just right. I wonder why something is not done to warm the carburetter shell itself.

FRED T. STEERWOOD,
Air Mechanic, R.N.A.S.

THE CASE FOR THE LONG STROKE ENGINE.

Sir,—I have been more than usually interested in the most recent numbers of your valued paper containing the discussion of the respective merits of the square and long stroke engine.

Mr. Norton does not compare the two in respect to cool running.

If, as Mr. Norton states, a long stroke engine of equal c.c. develops equal power to the square engine, on a higher gear, it will run cooler; also the greater the stroke in proportion to the bore the greater the surface area in proportion to the c.c., which means cooler running.

(Lt.) L. SAYER.

Sir,—Ably as Mr. Norton has stated the case for the long stroke engine in your issue of January 11th, there are still one or two points that appear to me to be rather obscure.

In the first place Mr. Norton is rather loose in his terminology. Why not use "pressure" in its scientific sense as "force per unit area," and work as the product of force into the distance through which it acts?

It appears to me that to equate "work" to "pressure," as Mr. Norton does "for simplicity's sake," is nothing short of scientific inaccuracy, which is to be avoided at all costs.

Again, does not Mr. Norton beg the question when he assumes that the total power transmitted by one stroke of the long stroke engine can be equalled by one of the

shorter stroke and then proceed to show that the short stroke would, *cæteris paribus*, only do 80% of the work of the long stroke?

Apart from minor considerations, surely the question is one of leverage. Given two engines (long and short strokes respectively) of equal capacity, working for any one stroke between the same two pressures P_1 and P_2 (the latter the difference between the pressure inside the cylinder and the atmospheric pressure at the moment the exhaust valve opens)—in the one case we have a greater force acting over a shorter distance, and in the other *vice-versâ*. The product of the two represents the work done, which, apart from defects in transmission, friction equals power transmitted. Hence "A.A.S.'s" assertion that the total "power" transmitted will be equal. It is quite obvious to the reader who has removed the blinkers of bias that this is what "A.A.S." is driving at.

We all know too well "the peculiarity of the long stroke engine of hanging on under load at low speeds especially," and surely no fairer criticism of this could be possible than to state that it "is not a help to long life for the bearings." Yet Mr. Norton inadvertently makes of this peculiarity an unqualified asset to the long stroke. Surely the fact of the matter is this. Every petrol engine, properly balanced and constructed, delights in "revs." "Revs" mean power and better balancing, and when properly lubricated every engine will stand up to the work, witness the four-speed A.B.C. Keeping up the revs. for this engine means "maximum of efficiency with maximum of refined running." But this is just what the long stroke does not do when it thumps over the brow of a long hill.

The section on "cylinder wear and piston ring pressures" is quite sound, and I think that here we have the explanation of the peculiarity of the long stroke of "hanging on under load."

I do not understand, however (perhaps Mr. Norton will explain), if we are dealing with two engines of the same capacity, where the increased angularity of the long stroke connecting rod *necessarily* comes in.

Oswestry. (Rev.) W. A. JONES, B.A., B.Sc.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—Allow me to say a few words in reply to Messrs. Mullis, Cope, and Marks.

First of all, I should like to contradict their statements *re* experience. I have had quite enough experience with flat twins to realise their sterling qualities, and I certainly admit that they are very nice machines for town work, but I absolutely refuse to withdraw my statement about the engine pulling itself over in the frame.

Even if they *know* it is impossible, I can only reply that I have *seen* it happen, have verified the fact by testing the alignment of the sprockets, and can find several other people who have observed the same thing.

I do not judge a motor cycle from my ability to drill holes in the radiator fins, but, having had several years experience in the "shops," I know what I am drilling, and how to do it.

Perhaps Messrs. Mullis, Cope, and Marks have never experienced overheating on their Utopian Americans, and have consequently never heard of the well-known practice often used in the T.T., especially before cooling was brought to its present efficiency, of putting small copper tubes and springs through the fins to assist the cooling.

In conclusion, I may point out that there are not many makes of machines that I have not ridden, studied, and inwardly digested, and I do not remember a machine with quieter timing gear than the A.J.S. Disclaimer as usual.

H. St. V. ADDENBROOKE.

Sir,—I have read Capt. A. Lindsay's letter in your issue of the 11th inst., and regret that this is not sufficiently convincing to induce me, as he requests, to modify my views that a long induction pipe does not affect carburation.

If he means that on a cold day, and with the carburetter not heated in any way, the long induction pipe is inferior, I quite agree with him, but, given induction pipes of similar temperature and under the same conditions, a long induction pipe is far superior, produces a more regular beat of the engine, and is economical in fuel.

In car practice the carburetter or induction pipe is invariably heated, apart from the heat conducted from the cylinder walls of the engine. In motor cycle practice the general impression that heating is unnecessary has arisen principally from the fact that the carburetter is placed so close to the cylinder that the short induction pipe is actually heated by direct conduction from the cylinder, and to quite a reasonable extent.

The flat twin is a totally different proposition, as the carburetter is farther away from the cylinder than in probably any other engine, and manufacturers, not realising the enormous benefits of heated induction, have not paid sufficient attention to this point.

On the A.B.C. machine the carburetter was thought to be quite sufficiently heated until, on one or two excessively cold days, difficulties were experienced for the first two or three miles. Increased heating was applied with vast improvement in running at each attempt, and the heating is now so efficient that the carburetter itself is almost too hot to bear the hand upon.

The manufacturer of one of the best known carburetters in the world to-day once told me that, if he could, he would have a blowpipe playing on the side of the carburetter the whole time, and a long induction pipe to give the petrol time to vaporise thoroughly.

Capt. Lindsay surely is rather stretching the point when he states (referring to "Ixion's" trouble with a flat twin on an exceedingly cold night) that this experience comes at a very awkward moment for those who are trying to persuade us that long exposed induction pipes are an advantage. Perhaps he will be good enough to point out who used the word "exposed" as a *desideratum* in induction pipe design.

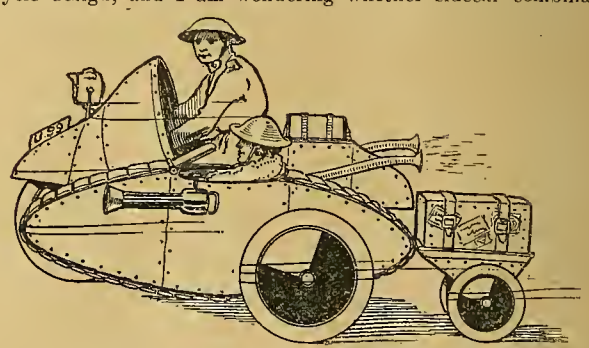
I am afraid that I cannot quite understand the following paragraph in Capt. Lindsay's letter: "If an engine can indulge simultaneously in an overheated sparking plug and a refrigerator inlet pipe, what constitutes a 'hot side'?" If he desires information on this point, I referred to it at some length in my article in your issue of December 7th, 1916, wherein I showed that an exhaust valve that is adjacent to one side of the cylinder has the effect of considerably increasing the temperature of that side of the cylinder, with the result that the cylinder walls are distorted, with undesirable effects upon the piston and piston rings. If, on the other hand, the paragraph in question is intended sarcasm, I have no desire to discuss this point further, and I do not doubt that the majority of your readers desire technical matters to be discussed in a technical manner.

With regard to the letter by "A.A.S." in your issue of January 4th, together with his sketch showing the valves at an angle in the head, as found in many aero engines of high efficiency, I might mention that I built large engines with valve gear of this type some years ago. We also manufactured cylinders of this type for our 500 c.c. engine early in 1915. Our speed model C is destined to have this valve gear (with slight modifications to suit air-cooled practice) immediately we resume our motor cycle production. GRANVILLE E. BRADSHAW.

A POST-WAR MODEL SIDECAR.

Sir,—No doubt the war will have a great effect on motor cycle design, and I am wondering whether sidecar combination makers will supply a model to suit our "Tank" officers and men after the war. Possibly the design I enclose will appeal to them. ROYAL SUSSEX.

Eastbourne.



Will battlefield fashions develop thus?

A WINTER ROAD TEST OF A LADY'S MODEL FLAT TWIN.

I HAD long promised myself a test of the lady's model Douglas, and one foggy and miserable morning a few weeks ago, to my pleasure, I received a wire from the London depot notifying its arrival. Some thoughtful person had left just enough petrol in the tank to cover the road distance between the depot and home. The motor cycle was new, spotlessly clean, its plated parts reflecting one's image in various distortions. In striking contrast, the roads were about as filthy from the trampled snow as I have ever seen them. It went to my heart to ride the mount for the first time under such unfavourable conditions, but after all what are motor cycles manufactured for but to drive, both in good and bad weather?

It was the model known as the X model, with the well-known 2¾ h.p. engine and open frame. The three-speed gear box, clutch, and kick starter are similar to those of the 4 h.p. model. The gear handle was already in the neutral notch, so I flooded the carburetter and gave the kick starter a mighty kick. I have been accustomed to handling a big twin, and the mighty thrust not only started the engine, but almost upset the balance of both myself and the machine. It requires no superhuman strength to start the Douglas, as the engine depends more upon revolutions than compression for its efficiency.

The frame is low and the large, comfortable footboards offer many changes of position. The specification is too familiar to make it necessary to dwell upon details, and the design has been well thought out for the lady rider. One feels so near the ground and the pull of the engine is so regular that, although I rode the mount through inches of mud and slush, and again on a frosty morning, when the surface of the road was almost as slippery as glass, there was never any tendency to skid: none of that "tail-wagging" that even experienced motor cyclists find nerve wearing.

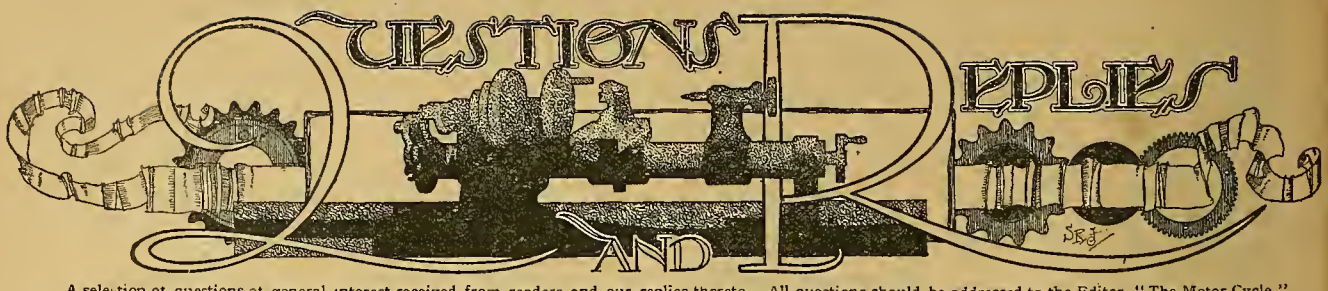
Efficient Mudguarding.

The aluminium covers give the motor cycle a very smart finish; these are held by butterfly nuts that are the work of a minute to remove with nothing but Nature's tools, the fingers. A small hinged door in the aluminium even saves one this trouble when access to the rear plug is required. The rider is well protected by the flanged mudguard; the front mudguard is so ample that I noticed when riding through puddles that a small stream of water (which would on many machines find a resting place on the rider's skirt) was thrown along in front of the footboards. This guard might with advantage be copied.

I practically lived on the machine for some days, and have nothing but praise for the rapid acceleration and even running of the little engine; the machine is light to handle and easy to drive and manage. No lady rider could wish for a better solo mount. There is just one small point in which improvement can be suggested — that is, when the foot clutch is out the pedal interferes with the steering by catching in the front mudguard flange. This, however, can be easily remedied by a crook being made to allow for clutch pedal, and no doubt such a minor point will soon be remedied. I *was* sorry when the Douglas had to go back.

MAY WALKER.

A winter test of a lady's Douglas, a machine possessing a flat twin engine of 2¾ h.p., three-speed gear, and kick-starter.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Transferring a Registered Number.

I wish to have the number which is on the motor cycle I have just purchased second-hand transferred to my name. Will you please tell me how much the transfer will cost, and to whom should I apply?—H.G.

The transfer of a registered number costs one shilling, and application must be made to the county council where the machine was registered.

Removing the Gudgeon Pin.

My machine is a 2¼ h.p. two-stroke, 1914. Will you kindly tell me the correct method of removing the gudgeon pin? Both ends appear to be of the same size and to be fixed with copper rings.—W.

Unless the piston or ends of gudgeon pin are marked "in" or "out" to indicate which is the larger end of the taper it is probably simply parallel, and can be driven out in either direction. Take care that you support the piston well while driving the pin out.

Starting a Single-geared Lightweight.

I have a 2¾ h.p. two-stroke with which I experience difficulty in starting. It will start all right if I run with it for a few yards, but I would like it so that I could paddle it off from the saddle. This it will not do, even when warm. I have tried various size jets (Amac carburetter). The magneto timing is right, and corresponds with the makers' catalogue. It is a Dixie magneto. I am not desirous of repeating the acrobatic performances of a few years ago.—W.B.

A single gear machine will seldom start easily by paddling it off. The only thing to render starting as easy as possible is to go over everything, and make sure all adjustments are right, such as plug points clean and adjusted rightly; a gap of 1 mm. is about correct. Contact points clean and breaking properly, about .4 mm. Carburetter clean and the correct sized jet fitted. A fairly large jet is wanted for easy starting; when once started, if the right jet is fitted, you should be able to run with air lever fully open, but for starting the air should be closed and about quarter throttle given. What is wanted is a rich mixture, and only a little of it. Make sure that there are no air leaks in the induction pipe or crank case; a leaking oil pipe will sometimes give trouble on two-strokes, by allowing air to enter crank case.

Intermittent Misfire.

I have a strange trouble with my motor cycle, and cannot master it. Can you assist me? The machine is a 1914 2½ h.p. two-stroke; it seems to have plenty of power, and is as speedy as usual. Compression is good. On the road it misses fire about one explosion in twelve continually, and on the stand it simply will not two-stroke: the engine travels at a terrific speed, and loud reports keep coming apparently from the silencer. I have had the engine taken down twice, cleaned, etc., by good, reliable mechanics, also I have written to the makers, and they are at a loss to explain it. Petrol pipe and carburetter are perfectly clean, also magneto (Ruthardt) gives a good, fat spark, and I have tried about six different plugs which have been tested in other motor cycles. When running on the stand, if I apply brake hard the machine runs about the same as on the road.—F.W.R.

It is extremely difficult to advise you without seeing the machine, as so many small defects may exist which to the unskilled eye may appear to be in order. A two-stroke will hardly ever run evenly on the stand or when running light. The most likely cause of the intermittent misfire is some fault in the ignition system—probably the contact breaker, the contact points of which may be inclined to stick at intervals. See that the rocker is quite free, and that the points are breaking properly and separating about .4 mm. Also see that the carbon brush and holder are in good order and quite clean. The reports from the silencer also indicate faulty ignition. Too large a jet causes four or eight-stroking, while too small a jet or one which is choked will cause popping in the carburetter. We think, however, the trouble lies in the magneto, and if you very carefully overhaul all parts of this your trouble will cease.

DELAYS IN POSTAL DELIVERIES.

In view of depleted staffs, the curtailment of railway services, and the consequent delay in delivery of mails, readers will greatly assist by forwarding communications (including advertisements) as much as possible in advance of the dates of the issues for which they are intended.

Sticking Rocker Arm.

My magneto (Bosch ZE1) rocker arm sticks. How is this removed? I understood the whole contact breaker could be removed by simply withdrawing the centre screw, but it will not come off, though this screw has been removed. I do not care to use much force in case there should be some other fastening than this screw. If you will assist me I shall be grateful.—A.M.

To remove the contact breaker rocker arm remove the centre screw and prize the contact breaker off by means of two small screwdrivers. It is fitted by means of a taper and key. If done carefully the rocker arm can be removed without disconnecting the main springs by levering it carefully out of its bearings by means of a penknife or small screwdriver. If you cannot remove it this way you will have to remove one of the small screws which holds the spring to the rocker. When removed from the contact breaker body you can reamer out the fibre bush by means of fine emery cloth wrapped round a match.

Running on Substitutes.

I am running a 7 h.p. Indian on a white oil substitute with 10% petrol. It runs well, but "soots up" quickly. Would naphthalene balls added to this mixture stop the "sooting up," and if so, would there be any fear of explosion of the tank on a hot day? I shall be greatly obliged if you will answer the above question.—J.H.B.

The sooting, or oiling, up which you experience when running on petrol substitute is most likely due to insufficient heating of the mixture before entering the cylinders. All incoming air should be drawn from some main portion of the engine by means of an air scoop. If an ordinary Indian carburetter is fitted, this fitting is, of course, standard. In addition, the inlet pipes should be either warmed by means of a heated jacket or be heavily lagged with asbestos string and insulating tape. From personal experience, we have never found much gain by using naphthalene balls and similar specially prepared compounds, but we have heard of a number of riders who report very favourably upon their use. Most of our correspondents writing on the subject claim that when using petrol substitutes the naphthalene balls give sweeter running and less carbon and soot. The number of balls to be used would be about three to each gallon. There is no danger attached to their use.

Lubrication with Paraffin.

My baby two-stroke being petroil lubricated (which I find quite satisfactory), is it advisable to attempt to run on paraffin?—G.E.W.

Provided you arrange for the mixture to be heated before entering the engine, there is no reason why you should not run on paraffin, or at any rate a percentage of paraffin. You may find a slightly larger jet desirable owing to the heavier nature of the fuel. The oil mixture will work equally well with paraffin, provided proper provision be made to ensure perfect evaporation of the paraffin.

Starved Carburetter.

I have a Coventry Eagle two-stroke motor cycle which is very difficult to start up. It has been running on lubricating oil and petrol mixed—in the same tank. Also, when on the road, it will take but little air, sometimes going better with the air entirely shut off. Any suggestion will be gratefully received.—EAGLE.

Your trouble is evidently due to a choked or starved carburetter, or to having too small a jet fitted. When the petroil system of lubrication is used the oil frequently becomes congealed in the carburetter, so causing the jet and other working parts and passages to become choked up. If thoroughly cleaning out the carburetter and jet does not effect a cure, try fitting a slightly larger jet. Make sure all inlet joints are air tight and not causing air leaks.

Tips for Scott Riders.

I have purchased a Scott motor cycle, and I would like to have a few hints and tips on this machine. I should like to have the experience of one who has been the owner of a 1914 Scott machine.—T.J.D.

Pay special attention to lubrication. The big ends of this engine are provided with roller bearings, and the cylinders being water-cooled, the engine requires very little oil. Do not make the mistake of over-oiling. We find that the best plan is to keep the plunger of the lubricator clipped down, and depend upon the suction of the crank case for the working of the drip; also note carefully that both cylinders are getting the same quantity of oil. If you find that one cylinder is getting an excess, the supply can be modified by taking out the small nipple contained in the oil pipe on that side, and closing it up slightly by carefully tapping with a hammer. We would also recommend you to make a careful scrutiny for air leaks. Test the crank case joint by dropping oil on to it when the engine is running, also test the pin holes which secure the rods by which the cylinders are held on. The slightest air leak either about the crank case or in the induction pipe will entirely upset the smooth running of this engine. With regard to transmission, see that the countershaft is in perfect alignment with the engine. Do not be tempted to correct chain tension by running the countershaft out of alignment, or chain troubles are sure to ensue. For further advice on this subject see *The Motor Cycle* for September 14th, 1916.

Belt Slip.

I have a 3½ h.p. Rudge-Multi motor bicycle and sidecar. I find that belts are apt to slip badly. Is there any belt on the market which lasts and does not slip? Leather belts are the best I have tried up to now.—G.T.H.

Your belt probably slips through the pulleys being of the wrong angle. The correct angle is 28°. Leather belts are very apt to cause the pulley flanges to wear badly owing to the grit they collect. You should experience no belt slip, except perhaps on the lowest ratios, provided the pulley flanges are not worn.

Too Large a Jet.

I have a 2½ h.p. motor bicycle fitted with B. and B. carburetter. I find that I get an increase of speed on opening the throttle, but after a little more than half open no increase in speed is obtained. The machine takes full air when the throttle is half opened. Should an extra air inlet be required to enable the machine to run on full throttle?—NOVICE.

The symptoms lead one to suppose that you are using too large a jet, causing the engine to choke when you open the throttle beyond a certain point. An extra air inlet might get over the difficulty, but when you can cure the trouble by fitting a smaller jet this is obviously the best and simplest thing to do.

Sidecar Breakages and Cleaning.

Can you tell me what is the strongest and most reliable motor cycle? I have a 1915 3½ h.p. single with rather a heavy sidecar. This machine never causes me any engine trouble, but after anything of a ride I generally find something broken, and, as a rule, some nuts are off. I ought to say that for safety's sake I have had my sidecar fixed further from the machine than sidecars are as a rule, and this no doubt causes strain, and accounts for the trouble I have in losing nuts, bolts, etc., after anything of a run; but I think perhaps a stronger made machine would suit me better. Can you advise me? I should also like to know how a motor cycle ought to be cleaned. My man always washes it with water, but the people at the garage where I put up in our nearest town say it ought not to be washed with water, as it spoils the bearings.—R.M.C.

We regret that we cannot recommend any particular make of machine for obvious reasons. 3½ h.p. is hardly sufficient for serious sidecar work. A machine of at least 4 h.p. with two or three speeds and chain drive is really the most suitable type. If the sidecar is not correctly lined up, this might easily account for breakages. See that the sidecar is parallel with the centre of the motor cycle, and that when on level ground the bicycle stands perfectly vertically. Unless you thoroughly wash the machine in paraffin afterwards it is not advisable to wash the mud off with water. If, however, the worst is washed off with water do not let it go round the wheel bearings more than can be helped.

Clutch Slip.

I should be very much obliged if you would give me a little assistance respecting a trouble I am just experiencing with my machine. I run a 1913 3½-4 h.p. sidecar outfit. Armstrong three-speed hub gear. Up to just recently everything has been perfect, but I had occasion two months ago to renew the gear wheels in the hub gear, since which time there has been a slip somewhere. There is no trouble when running at a fair speed on the level, but directly I reach an incline or open out a little more the engine commences to race on any of the three gears. I have had the gear down again and thoroughly washed out the clutch and also gears, but there is very little improvement. I might say that I have fitted a new belt, so that there is not much chance of this being the trouble. I use ordinary thin engine oil for lubricating; would this be too thick? I sometimes have trouble in getting gears to change.—S.H.C.

We should say that the trouble is undoubtedly due to clutch slip. Ordinary engine oil is rather too thick, and we should recommend you to use oil suitable for plate clutches. Possibly stronger clutch springs are necessary. Make quite sure that everything is perfectly tight and in line as regards the control mechanism of the gear, otherwise you will have difficulty in changing. It is especially important that the change speed lever is a tight fit on the top tube and cannot possibly turn or shake loose. See the article on the subject in *The Motor Cycle* of December 7th, 1916, page 490.

EXPERIENCES WANTED.

"A.P.E." (London). — "Oxigene" mixed with petrol to cause decarbonisation of engine.

"S.T.C." (Beaconsfield).—Speed and hill-climbing capabilities of a racing Harley-Davidson or road-racing Indian.

RECOMMENDED ROUTES.

LOWESTOFT TO MANCHESTER.—F.K.B.

Lowestoft, Beccles, Norwich, East Derebam, Swaffham, King's Lynn, Swineshead, Sleaford, Newark, Mansfield, Chesterfield, Baslow, Chapel-en-le-Frith, Stockport, Manchester.

HARROGATE TO KIDDERMINSTER.—R.W.

Harrogate, Wetherby, Aberford, Ferrybridge, Doncaster, Mansfield, Derby, Burton, Lichfield, Sutton Coldfield, Birmingham, Halesowen, Kidderminster.

WOKING TO TEWKESBURY.—J.B.

Woking, Chobham, Bagshot, Wokingham, Reading, Wantage, Lechlade, Cirencester, Colesbourne, Seven Springs, Cheltenham, Tewkesbury. Approximately 103 miles.

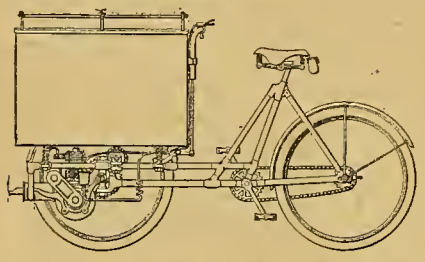
BUILTH TO FOLKESTONE.—X.Y.Z.

Builth, Hay Hereford, Ledbury, Tewkesbury, Stow-on-the-Wold, Chipping Norton, Woodstock, Oxford, Henley, Maidenhead, Windsor, Egham, Chertsey, Ripley, Cobham, Leatherhead, Dorking, Reigate, Redhill, Oxted, Westerham, Seal, Maidstone, Charing, Ashford, Hythe, Sandgate, Folkestone. Roughly 280 miles.

PATENTS by Eric W. Walford

A Tradesmen's Carrier.

Upon the steerable frame, which carries the luggage box, is mounted an engine, which, in the case shown, is of the two-



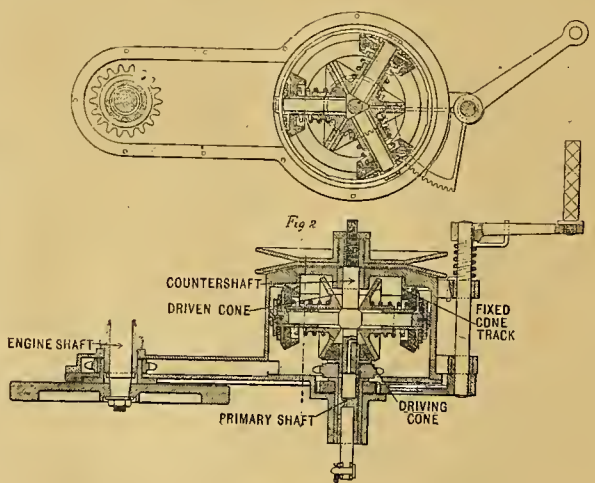
stroke type. This engine drives through a chain on to a countershaft, having a differential gear, the countershaft in turn driving the road wheels through spur gearing arranged in oiltight casings.—A. E. Lambourne and John Warwick and Co., Ltd., No. 102,110.

An Ingenious Friction Gear.

One advantage of friction gearing is that it provides a gradually variable effect, and the present construction is a neat adaptation of such gearing to a motor cycle countershaft. The drive passes from the engine-shaft to a sprocket keyed upon the primary shaft of the gear. This primary shaft can slide through the sprocket, and upon its inner end is fixed the clutch and driving cone. Co-axial with the primary shaft is the countershaft, and the latter telescopes within the former for support. The countershaft carries a number of radial arms, or spokes, and upon each of these is freely mounted a cone driven from the primary cone. Upon each radial arm is also mounted an outer cone, which is keyed both to the radial arm and to the corresponding driven cone. The outer cones run upon a fixed track in the gear housing, and between the pairs of cones on each radial arm is a spring which forces the driven cone inwards into contact with the driving cone. The gear is operated by sliding the primary shaft in and out through the keyed driving sprocket. When the shaft is in its outermost position the driving cone is free of the driven cones, and therefore revolves freely without transmitting its motion to these cones. On moving the driving cone inwards it first engages the driven cones near their peripheries, rotating these at a reduced velocity. These in turn rotate the outer cones on the radial arms, and these cones run round the fixed track carrying the radial arms, and consequently the countershaft, with them. As the driving cone is moved further inwards the driven cones are pressed apart against the springs, and the gear ratio is gradually varied. The countershaft is shown with a belt pulley for the final drive, and a kick-starter mechanism is incorporated, acting on a spur gear on the primary shaft.—G. J. Dallison, No. 101,896.

An Improved Release Valve.

By the valve shown, which is intended for use with two-stroke engines, it is not only possible to provide a free release for the gases, but a variable compression effect is obtainable. The body A screws into the combustion chamber and forms a seating for a poppet valve B, which is normally held closed by a light spring C. Above the domed washer on the valve stem is a stronger spring D, and the effect of this spring can be varied by adjustment of the abutment E, which is actuated by the bell crank lever shown. In use, when full release is desired, the disc E is moved downwards until the pressure of the spring D overcomes that of the spring C and the valve B opens. To provide a decompressor effect, the degree of pressure imparted to the spring D is such that it will open the valve B against the spring C, but allows the valve to close under the pressure produced when the piston has moved a certain distance up the compression stroke. The valve then remains closed during the firing stroke, and opens again when the pressure in the cylinder falls to zero.—J. Martin, No. 102,185.



Enfield Two-stroke Handbook.

A third edition of the Royal Enfield treatise dealing with their two-stroke model has just been published. The booklet is splendidly produced and illustrated like all Enfield productions.

SPARKLETS

No Address.

Messrs. C. Binks write stating that £2 12s. 6d. has been sent to them by a Mr. R. Ditwell without giving an address. The money will be returned should the goods not be required.

A New Catalogue.

We have before us the catalogue sent out by J. Pedley and Son, rubber manufacturers, Birmingham. It is a very comprehensive list, and exceedingly well illustrated. Everything a motorist requires in the manufacture of which rubber plays a part is shown.

Force Feed Oil Pump.

With reference to the Tanner lubricating pump described in our last issue, we are asked to state that models for testing purposes are in course of construction, and arrangements are being made for the manufacture of large quantities. Applications should be made to the inventor, Mr. R. L. Tanner, Lynmouth, Earlsdon Avenue, Coventry.

A Satisfactory Dividend.

Messrs. Simms Motor Units, Ltd., Percy Buildings, Gresse Street, Rathbone Place, London, W., advise us that for the financial year ended June 30th, 1916, a dividend of 25% has been declared on the paid-up capital of the company. An amount of £20,680 1s. 2d. has been carried forward, after making ample provision for depreciation, and the transfer of £4,000 to the reserve account.

Locating Faults.

We have at hand a booklet from the Lodge Sparking Plug Co., Ltd., entitled "Locating Faults in the Petrol Engine." The method the author has adopted in tabulating the symptoms, the troubles, and the remedies is admirable. The veriest novice will, in these concise hints, be able to grasp readily the remedies for various faults he may have with his engine. The booklet will be sent free to any reader who cares to apply to the Lodge Co., Rugby.

The Searle Unburstable Inner Tube.

We have received information that the County Chemical Co., Ltd., Chemico Works, Bradford Street, Birmingham, have taken over the sole selling rights for the United Kingdom and certain foreign countries of the Searle Unburstable inner tube. Our readers may remember that this tube has three plies of canvas incorporated in it, rendering it non-stretchable for the greater part of its circumference. On the tread of the tube is a pleat filled with elastic rubber, which allows the pleat to flatten out on the tube being expanded. The advantage of the tube is that, in the case of a tyre bursting, the tube is protected from damage. Every tube is tested to a pressure of 80 lb., unsupported by a cover, previous to being sold.

We regret

BOWDEN Wire, Limited, London, regret to announce that, being wholly engaged upon production for the British and Allied Governments, they are unable to execute any orders for private purposes until further notice. They have in stock certain goods suitable for replacements. Customers are invited to state their requirements in this respect, and, if possible, these will be met.

BOWDEN WIRE LTD LONDON

Godbolds

A manufacturer who supplies Magneto Parts from stock.

Recollect, we can supply the worn or missing part which is required to restore your magneto to its original condition. We manufacture "spares" for magnetos of all makes, so are able to quote attractive prices. If your machine needs thoroughly overhauling, send it on, and we will return it like new.

SIMMS MOTOR UNITS, LTD.,
PERCY BUILDINGS, GRESSE ST.,

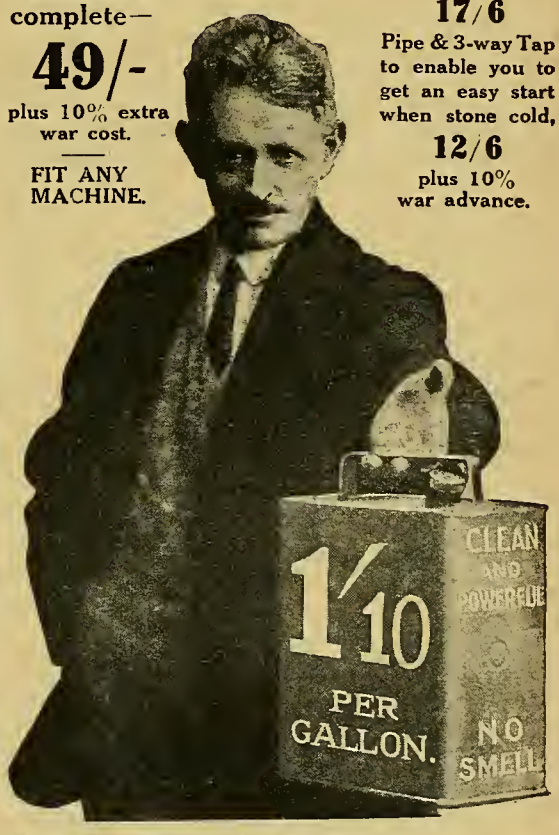
17/6

Pipe & 3-way Tap to enable you to get an easy start when stone cold,

12/6

plus 10% war advance.



READ!

MY 3-PHASE JET DAMPING CARBURETTERS

have such perfect vaporising properties that they enable you to use fuel at **1/10** per gallon in 42-gallon casks, which you are allowed to keep on your premises. Casks **12/6** each, returnable at **10/-** each. Your engine will tick over dead slow, and pull dead slow in traffic, yet give the full power. It is almost impossible to tell you are not running on petrol at **3/-** a gallon. It cannot damage your engine or soot it up and makes Motor Cycling possible in these times.

I give you my personal assurance of the truth of what is stated above. Please send at once for full particulars of the carburetter, and also for my Treatise on Carburation, and terms of One Month's Approval Trial.

C. BINKS, Ltd., Eccles.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed ——— & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle" Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

CRESCENT, 1916, 2½h.p., 2-speed, 2-stroke, £9 worth accessories, including speedometer, Stewart warner; cost £46, nearest £30.—Details, Fowler, Brooks' Garage, 15, Llanover Rd., Plumstead. [X4906

Douglas.

1911 Douglas, exceptional condition; £17.—248, Bentley Rd., Doncaster. [X5112

DOUGLAS, 1912, clutch, 2-speed, kick start, little used.—5, Chatsworth St., Derby. (D) [X455?

IF You Want a Douglas, visit or write The Walbro Garage, Ely. We have them. See below.

1915 Douglas, 2¾h.p., 3-speed, Lucas head and rear lamps, absolutely as new, ridden about 200 miles only; £48.—Below.

1915 Douglas, 2¾h.p., 2-speed, P. and H. lamp, Lucas rear, Lucas horn, footboards, and metal leg shields, spare tank for running on substitute; £44.—Below.

1915 Douglas, 2¾h.p., 2-speed, P. and H. lamp, Lucas rear and Lucas horn, Stewart speedometer special large plated exhaust pipes, tyres almost new, very fast; £47.—Below.

1914 Douglas, 2¾h.p., 2-speed, T.T., all in splendid condition, lamps, horn, etc.; £32.—Below.

THE Walbro Garage, Ely, Cambs. 'Phone: 48. [X4978

DOUGLAS, late 1914, clutch model, various spares; £35.—Hunter, Darlington Rd., Ferryhill. [X494?

1910 Douglas, single speed, as new; exchange or sell £19.—Singleton, 15, Enmore Rd., South Norwood. [X501?

DOUGLAS, 1913, 2 speeds; £30.—Smith, 16, Haverstock Hill, opposite Chalk Farm Tube Station. [7639

1912 Douglas, 2 speeds, footboards, complete [illegible] horn, numbers; £22.—Cross, Jeweller, Rotherham. [X5070

1913¾ Douglas, 4,000 rev. engine, very fast, climbs 1 in 2½; £30.—Meeson, 35, Park St., Islington, London. [7595

1914 Douglas 2-speed, lamp, horn, etc., tyres as new, splendid engine, fast; £39.—Gibb, Gloucester. (D) [X5049

DOUGLAS, 2¾h.p., £15/10; 1913 2-speed, £34/10; 1914 2-speeds, £39/10.—Motor Exchange, Horton St., Halifax. [7650

DOUGLAS, 1914, T.T., 2¾h.p., good tyres, in good condition throughout; £35.—John Chaplin, Fulbourn, Cambs. [7482

DOUGLAS.—Wholesale and retail West of England agents; write us your requirements.—Moffat, Yeovil Tel.: 50. [585

1913 Douglas, 2¾h.p., 2-speed, T.T. model, in fine trim, lamps, etc.; £29.—Jones, Garage, Broadway, Muswell Hill. [7694

COLMORE Depots, Birmingham, Manchester, and Liverpool and Leicester, for earliest delivery of Douglas motor cycles. [0800

DOUGLAS, 2¾h.p., fine order, new tyres, plating enamelling new, only wants seeing; £17.—14, Doubrooke Rd., West Norwood. [0869

DOUGLAS, 1915, 4h.p., coach combination, faultless condition; £60; part exchange entertained.—124 Walton Rd., Hampton Court. [X5121

2¾h.p. Douglas 2-speed Model, fitted with a light side-car; the combination £30, guaranteed.—Wanchope's, 9, Shoe Lane, London. [7580

1912 Douglas and Sidecar, both good condition, fast reliable machine; rare bargain, £26.—6, Lorenzo St., Pentonville Rd., King's Cross. [7643

DOUGLAS, 1915, 2¾h.p., T.T., overhauled and re enamelled; £44; extended payments arranged.—Service Co., 292, High Holborn, London. [X4990

1915 2¾h.p. T.T. 2-speed Douglas and accessories in good condition; £42/10; seen any time.—Bonnde' Garage, 223, High Rd., Kilburn. [7472

DOUGLAS Specialists.—Gibb, Gough, London Rd Gloucester. Gibb, the International Douglas rider wioner of numerous cups and gold medals. [2216

DOUGLAS, 1914, 2¾h.p., 2-speed, T.T. bars, lamps and horn, fast, and reliable, good condition; £32 or nearest offer.—97, Malvern Rd., West Kilburn. [7435

1915 Douglas, 2¾h.p., 2-speed, Lucas acetylene lamp front and rear, speedometer, etc.; £37/10, no offers; private owner.—5, Raw Lane, Illingworth, Halifax, Yorks. [X5007

DOUGLAS, 1915, 3-speed, Colonial model, perfect condition, all accessories, mechanical horn, tyres almost new; seen any time; £40, no offers.—Terry, jun., Odiham, Hants. [X4945

NEW MODELS FROM STOCK.

ALLON, 2-stroke, 2-speed	£42	0
B.S.A., 4½ h.p., 3-speed, chain drive	£66	0
B.S.A., 4½ h.p., 3-speed, model K	£64	0
BROUGH, 3½ h.p., T.T. model, 2-speed	60 gns.	
CALTHORPE, 2-stroke, 2-speed	33 gns.	
CALTHORPE-J.A.P., 2¾ h.p., 2-speed	38 gns.	
ENFIELD, 2-stroke, 2-speed	42 gns.	
ENFIELD, 3 h.p., twin, 2-speed	88 gns.	
ENFIELD, 6 h.p., Combination	90 gns.	
ENFIELD, 6 h.p.. Combination, with Lucas dynamo lighting set	105 gns.	
JAMES, 2-stroke, 2-speed	£42	0
JAMES, 3½ h.p., twin, 3-speed	£69	0
JAMES, 4½ h.p., Combination	£88	0
NEW IMPERIAL, 2½ h.p., 2-speed	39 gns.	
NEW IMPERIAL, 2½ h.p., 2-sp., clutch and kick-starter	46 gns.	
ZENITH-GRADUA, 3½ h.p., twin	£62	0

EXCHANGES

We specialise in exchange transactions, and will allow full value for your old Motor Cycle or Light Car in Part Payment for any new one

SECOND-HANDS.

The following is a selection from our large stock of machines of all types:

CLYNO, 1914, 6 h.p. Combination, Lucas electric lighting set, speedometer	£68	0
JAMES, 1915, 2½ h.p., 2-stroke, 2-speed, Lucas lamp set, rear lamp and horn	£33	0
ALLON, 1915, 2¾ h.p., 2-stroke, 2-speed	£33	0
MATCHLESS, 1913, 8 h.p., 2-speed, clutch, & kick-starter, all accessories	£38	0
ZENITH, 1913, 3½ h.p., Gradua gear	£30	0
PREMIER, 1915, 3½ h.p., countershaft, 3-speed gear, lamps, and horn	£45	0
CALTHORPE, 1915, 2¾ h.p., 2-stroke, 2-speed, headlight, rear lamp, horn, and speedometer	£28	0
VINDEC, 1911, 5 h.p., 2-speed, headlight, rear lamp, horn and coachbuilt Sidecar	£22	0
CHATER-J.A.P., 1912, 8 h.p. countershaft, 3-sp. gear, all chain drive, and coachbuilt sidecar	£45	0
DOUGLAS 1915 2¾ h.p. War Office model	£50	0
ALLDAYS MATCHLESS, 1915, 3½ h.p., coach-built Combination, 3-speed, lamps and horn	£45	0
TRIUMPH, 1914, 4 h.p., 3-speed	£40	0
JAMES, 1916, 2¾ h.p., 2-stroke, 2-speed, lamps, and horn	£36	0
B.S.A., 1916, 4½ h.p., 3-speed, all-chain drive, lamps, horn, and Canoelet Sidecar	£63	0
ROYAL ENFIELD, 1914, 3 h.p., twin, 2-speed	£32	0
DOUGLAS, 1910, 2¾ h.p., lamps and horn	£15	0
CALTHORPE-MINOR, 1914, 2 h.p., 2-sp., and free engine	£15	0
CALTHORPE-J.A.P., 1915, 2¾ h.p., 2-sp., lamps and horn	£30	0
BROUGH, 1916, 3½ h.p., T.T., 2-speed, headlights, rear lamp, speedometer	£53	0
NEW IMPERIAL-J.A.P., 2½ h.p., T.T. model, 2-speed, Cowey speedometer	£33	

Deferred Payments accepted for either New or Second-hand Goods.

EASTERN GARAGE CO.,

Official Repairers to R.A.C., A.C.U., A.A. & M.U.

MOTOR CYCLES FOR SALE.

Douglas.

DOUGLAS, 2¾h.p. T.T., late 1913, 4,000, perfect, very fast, climb anything normal on top; trial; deposit; owner in army 18 months; £33.—Newman, Cowpen Hall, Blyth. [7512

LATE 1914 Model V Douglas, not ridden till 1915, in excellent condition throughout, complete with Lucas lamps and horn, full kit of tools, etc.; £38.—Lewis, 65, Shakespeare Av., Bath. [7644

1913-14 2¾h.p. Douglas, clutch, lamp, new tyres, Stewart horn, special engine and carburetter, just overhauled; bargain, 33 gns.; guaranteed.—Curtis, St. Cuthberts, Norwich Rd., Thetford. [X4961

DOUGLAS, 1914, 2¾h.p., T.T., machine little used, in excellent condition, 2 Lucas lighting sets, horn, spare belt, knee-grips, etc., tank red and black; £38.—Gosse, Ferns, Southend Av., Darlington. [X4705

RIDER TROWARD'S, 78, High St., Hampstead.—1912-13 T.T. Douglas, 2-speed, perfect, 24 gns.; 1913 Douglas, new 1914, 2-speed, clutch, kick start, thoroughly overhauled, new tyres, fast, 32 gns. [7541

DOUGLAS, 2¾h.p., nearly new, W.D. model, complete with lamps, horn and tools; £57/10; easy purchase terms if desired; exchanges entertained.—Harrods, Ltd., Motor Cycle Dept., Basil St., Brompton Rd., London, S.W. [7462

Enfield.

COLMORE Depot, 31, Colmore Row, Birmingham, for immediate delivery of Enfields. [0801

ENFIELD, 1916, 6h.p., and sidecar, as new, guaranteed; £78/10; extended payments arranged.—Below.

ENFIELD, 3h.p., done 120 miles only, unscratched, speedometer; £52/10; extended payments arranged.—Service Co., 292, High Holborn, London. [X4992

ENFIELD 1916 6h.p. Combination, little used, guaranteed perfect, with accessories; £75.—Moss, Wem [X5059

ENFIELD 3h.p. Twin, 2-speed, free, pedal start, good order, fast; £20.—14, Dodbrooke Rd., West Norwood. [0878

1917 6h.p. Enfield Combination and accessories, as new; £85; seen any time.—Bounds' Garage, 223, High Rd., Kilburn. [7480

ENFIELD, 8h.p., 1914, sidecar, and 3 lamps, speedometer; £55; good condition.—Collyer, 286, High Rd., Wood Green, N. [X5122

ENFIELD 1912 6h.p. Combination, good condition, fast, absolutely reliable; £35.—The Cottage, King's Head Hill, Chingford. [7533

ENFIELD 1916 6h.p. Combination; a bargain, £69/17/6.—Wilkins, Simpson, and Co., 11, Hammersmith Rd., London. [7491

3h.p. Twin Enfield, Bosch, B. and B., good tyres, needs little attention; first £20 secures.—Gunning, H.M.S. Star, c/o G.P.O. [7452

6h.p. Royal Enfield 1913 Combination, in very fine order; £45.—Smith, 16, Haverstock Hill, opposite Chalk Farm Tube Station. [7637

BIRMINGHAM Controlling Agent, P. J. Evans, John Bright St.—1917 Enfield models actually in stock for immediate delivery.—See below.

1917 6h.p. Enfield Coachbuilt Combination, with apron and mat, 2 speeds, clutch and starter, 90 gns.; extra for hood and screen, £4/19; Lucas lighting set, 15 gns.; 8h.p. engine, £2 extra.—Below.

1917 3h.p. Enfield, solo or sidecar mount, 2 speeds, clutch, and kick starter; 55 gns.; sidecars from 7 gns.—Below.

1917 Enfield 2-stroke, 2¼h.p., 2 speeds, with free engine, clutch, 42 gns.—P. J. Evans, John Bright St., Birmingham. [X5038

1913 3h.p. Royal Enfield, 2-speed, kick starter, lamps, horn, tools, etc., good tyres and condition; £27.—Turner, Westbourne House, Twickenham. [7447

1914 Enfield Combination, speedometer, horn, Major F.R.S. set, sidecar and tail lamps, recently overhauled; £55.—Scott, High St., Westerham, Kent. [7518

1916 Enfield, 6h.p., sidecar, 2-speed, competition machine, guaranteed 60 m.p.h.; 63 gns.; very sporting.—245, Hammersmith Rd., London, W. [7509

1916 Enfield Combination, very little used, £82/10; also 1913-14 Enfield coachbuilt combination, £57/10.—Collier's Motories, Deal St., Halifax. [7652

1915¾ 6h.p. Enfield Combination, speedometer, horn, lamps, only run 1,500 miles.—Best offer to Walters, Grasmere, Eversley Rd., Sketty, Swansea. [7181

ENFIELD Combination, 1916, 6h.p., 2-speed, with lamps, horn, etc., splendid condition; £78.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C. [0491

ENFIELDS.—Birmingham Controlling Agent, P. J. Evans, for immediate delivery all models: Combinations and Solo mounts.—87-91, John Bright St. [7688

1915¾ Enfield 3h.p. Twin, kick starter, overhauled, not ridden past six months, good lamps, no generator; £25; seen by appointment.—Surveyor, Oakdene, Rottingdean. [X4699

ENFIELD Combination, 90 gns.; 3h.p. twin, £57/10; 2-speed, 2-stroke, £45; delivery from stock.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter, and Tavistock Rd., Plymouth. [0838

ENFIELD 1913 Combination, less body, 6h.p. twin, Bosch, 2 speeds (countershaft), speedometer; great sacrifice, 29 gns.; exchanges.—Wandsworth Motor Exchange, Ebner St., Wandsworth (Town Station). [7521

Who should hold Driving Licences?

THE action of the Northamptonshire Licences Committee in making a representation to the Home Office and Local Government Board urging that it should be made impossible to grant driving licences to obviously incompetent persons, such as those suffering from blindness, *deafness*, etc., has brought strong protests from motor cyclist readers. Whilst the committee are undoubtedly right in recommending that some discrimination should be made in granting licences to blind and limbless people, they are surely over-stepping the mark when they specifically include those who suffer from deafness. Many successful motorists of the present day are deaf, but no real danger to other road users has been proved on account of that affliction.

One of our correspondents, "SW149," points out a glaring inconsistency in this matter, viz., that whereas efforts are, on the one hand, being made to provide motor vehicles for men incapacitated in the war by arranging the controls suitably for men who have lost an arm or a leg, on the other we have an authority (?) actually urging that licences be withheld from people who are deaf. Personally, we do not see how a deaf man can be a danger to others if he drives carefully—and all who do not drive carefully are a danger whether deaf or not—and there can be no possible reason for refusing him a licence. A man does not steer by ear or avoid a collision because he hears another vehicle. It is bad policy to trust to the ear at a blind corner or dangerous cross roads, for even a man whose hearing is acute may fail to detect the sound of an approaching vehicle for a variety of reasons. A deaf man may occasion some delay to those who are overtaking him on a narrow road, but this difficulty can easily be removed by the use of a mirror on the handle-bar, and it cannot be said that deaf people are the only sinners in this respect.

Will New Motor Cycles be Cheap after the War?

OF all the absorbing problems which confront the motor manufacturer to-day, none is more engrossing than the question of prices after the war. It is not remarkable, perhaps, that there are conflicting views, one school being of opinion that it will take years before the prices of raw materials descend to their pre-war level, as well as normal cost of living, which factors alone will prevent any sudden decline in the price of new motor cycles as compared with those existing at the outbreak of war. The other school—and it is a strong and representative body—can see nothing but quantity production with the most modern labour-saving devices on the most advanced system, which they contend must inevitably lead to an all-round cheapening of manufacture with a corresponding reduction in selling price. But even this section does not anticipate any drastic reduction in the selling price of the highest class machines at any rate.

We have reminded our readers on previous occasions that the lavish equipment of munition works with the latest types of machine tools—many admittedly unsuitable for motor work—and the many new engineering factories erected since war broke out which will be seeking a new channel for their energies when this dreadful war ceases, must have their effect upon the question under discussion. The lightweight—particularly the two-stroke—offers the best possibilities for cheap and rapid production, and we feel that we shall not be far wide of the mark when we suggest that £20 lightweight motor cycles produced on a quantity basis will be no novelty when peace returns. The lightweight is an excellent stepping stone to the more ambitious and completely equipped motor cycle, so that the advent of the low-priced lightweight should not meet with disfavour from sections not interested in it from a manufacturing point of view.

An index to the advertisements in this issue will be found on the page facing the back cover.

A HOME-MADE KICK-STARTER.

How a Reader fitted his 3½ h.p. Zenith with a Foot-starter for Use with a Sidecar.

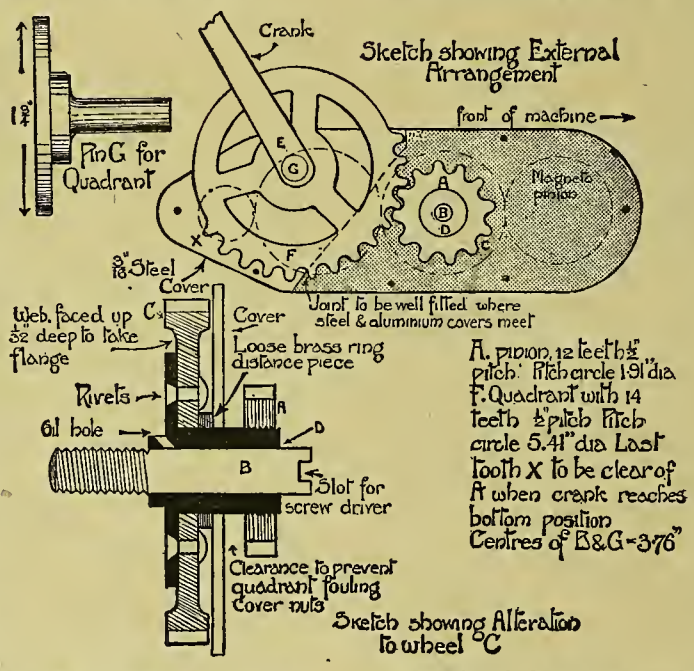
ALTERATIONS and improvements which can be carried out by motor cyclists themselves in their spare time always seem to me to be of more than usual benefit to the general rider, and incidentally in *The Motor Cycle* dated January 18th a correspondent raises the question as to the possibility of fitting a kick-starter to a 6 h.p. Zenith.

As I have recently carried out such an alteration to a 3½ h.p. machine of this make, which I purchased second-hand, it may be of interest to other Zenith riders if I give a brief description and rough sketches showing how it was done.

The only suitable place I could find was on the timing gear side, between the front and back footrests.

My magneto is gear driven, so I removed the intermediate wheel next to the magneto, and also the pin carrying it. One revolution of this wheel equals two and a quarter engine revolutions.

The alterations to this wheel were as follow. A 1in. hole was bored through the centre of the wheel C, and in this was placed a bush D, which was turned with a thin flange, and on the back of it a small boss was left to replace the original boss on the wheel, which disappeared in the boring process. The flange was then riveted to the web of the wheel, the rivets at the back being countersunk and finished off flush with the flange.



Sketch showing External Arrangement
Crank
front of machine
Pin G for Quadrant
Magneto pinion
⅜" Steel Cover
Joint to be well filled where steel & aluminium covers meet
Web faced up C to ½ deep to take flange
Cover
Loose brass ring distance piece
Rivets
Oil hole
Slot for screw driver
Clearance to prevent quadrant fouling Cover nuts
A. pinion, 12 teeth ½" pitch. Pitch circle 1.91" dia
F. Quadrant with 14 teeth ½" pitch Pitch circle 5.41" dia Last tooth X to be clear of A when crank reaches bottom position Centres of B&G=3.76"
Sketch showing Alteration to wheel C

The pin B was next made and fitted in the timing case to replace the short pin removed. This should be an easy fit in the bush D, and should be case-hardened to prevent seizing. The oil holes in the bush D and a large groove were necessary, owing to length of bearing surface.

A pinion A having twelve teeth ½in. pitch was next tapped 1in. thread to screw on to the bush D.

The aluminium timing gear cover was next cut as shown in the sketch of the external arrangement, and a steel plate, cut to shape as shown, was carefully fitted—special care being taken to make a good joint to prevent loss of oil from gear case. The steel plate was necessary to withdraw the weight on the pedal.

A hole 1 1/16in. diameter was next carefully cut in the aluminium half of the cover to allow the bush D to revolve without touching the cover. A brass distance piece, sufficiently thick to prevent the teeth of the wheel C touching the cover, was slipped on to D. This completed the actual alteration to machine.

An old pedal crank and chain wheel were next taken in hand. The chain teeth rim was removed from the three arms, and a piece of steel plate ⅜in. thick was cut to the shape shown and fitted to the arms. Fourteen teeth were cut and filed up to shape, the rest of the periphery being reduced to clear the wheel A. I find these fourteen teeth driving on to the twelve of the wheel A give about two and a half revolutions of the engine; and the position of the crank shown in the sketch is the best position for starting the kick. In place of the pedal I have a roller 4½in. long on a ¾in. pin. A flanged pin G to suit the hole in the crank completes the necessary parts.

The Assembling Process.

The pin B having been put in place, and the lock nut securely tightened up, the wheel C is put in its place (making sure first that the magneto timing is correct). The aluminium half cover is placed in position, care being taken that the brass distance piece is just free when the cover is pressed home to the timing gear casing. The wheel A is now screwed on to the projecting bush D. Place the steel cover on its four studs temporarily to mark off position of the flanged pin G. The top of this flange should come up to the top of the steel cover, so that the crank clears the ground. By holding the quadrant F in gear with A the exact centre for G can be marked on the steel cover. G is then attached by six ¼in. cheese-headed screws to the steel plate, the ends of the screws being filed off flush.

The steel cover can now be put in place and secured with the four nuts. (In my machine it was necessary to file a bit of flange G away to clear left-hand top nut,) This completes the job, and results have justified the time spent on it.

To start up I slide the quadrant on to the pin G, in the position shown, kick down to the bottom, and draw quadrant off when engine is running, and replace it in sidecar. (I never ride solo, but in such a case a clip could be fitted to machine to carry quadrant.)

It will be seen that when the pedal is at the bottom of the stroke the last tooth of the quadrant is clear of the wheel A, so no free-wheel arrangement is necessary. It is hardly needful to say that the quadrant and also the pinion teeth should be case-hardened.

"KICKER."

Petrol Filters.

I AM a little doubtful about the wisdom of mounting petrol filters just below the petrol tap. If really substantial bases or sockets for petrol taps were firmly fixed in tank bottoms the case would be different, but in present practice the average petrol tap is so lightly mounted in the tank that it will not stand a lot of spanner work even in careful hands, and is very apt to be ripped out or loosened by the average duffer operating a large adjustable spanner rather carelessly. My own filter has just choked, and I had to work very gingerly indeed with two special spanners in order to remove it without damaging the flimsy mounting of the petrol tap.

Some Cases in Point.

SOME advertising matter to hand, describing the new Woolf graphite lubricator, tells some amazing yarns about the efficiency of graphite. It is said that in one of the big car races in America in 1916 a driver who broke his crank case sump and lost all his oil raced for several miles on the smell of oil remaining in the engine, aided by powdered graphite inserted through the sparking plug holes. Or, again, that a motor car, deprived of all its cooling water by an accident to the radiator, was driven home with graphite added to the lubricant. Or, again, that graphite is the only possible lubricant for automatic composing machines in printing shops, which melt metal to form their type. I cannot vouch for any of these yarns, and American papers print some tall stuff. Anyhow it is beyond contradiction that at least one manufacturing firm builds its hopes of dividends on the elimination of oil from many motor car bearings, including some engine bearings, for its speciality takes the form of phosphor bronze bushes, the grooves of which are filled with compressed graphite instead of being left empty for the oil to travel along them.

The Woolf Graphite Lubricator.

ANY readers who wish to form their own opinions can choose between two methods of employing graphite. They can either buy a small tin of Oildag from their accessory dealer and mix it with the oil, or they can get the Woolf lubricator (handled in this country by Jarvis Bros., Middlesbrough). It takes the form of a fair-sized screw-down greaser with a shut-off tap at the bottom, and is mounted in the inlet pipe of a car or cycle engine. Once every fifty miles the tap is opened whilst the engine is running, and sufficient graphite is inhaled to last the engine for the distance indicated. The vendors make a great point of the value of introducing the graphite at the top of the engine, but I personally question whether the device scores in any other respect than that of saving the trouble of stirring graphite into the engine oil. The patent lubricator is obviously the quickest way of getting a good supply of the stuff on the cylinder walls; but if graphite is stirred into the oil, it must reach other parts of the engine more speedily and satisfactorily; and my own experience is that the connecting rod bearings are usually the parts of a motor cycle engine where lubrication is least perfect, and—in careless hands—most precarious. It is possible that the Woolf device is selling well in America, because it meets the peculiar case of the Ford, the magneto of which would be shorted if graphite were stirred into the lubricating oil, but in any case it is a handy fitting for graphiting cylinders.

Sparking Plug Coolers.

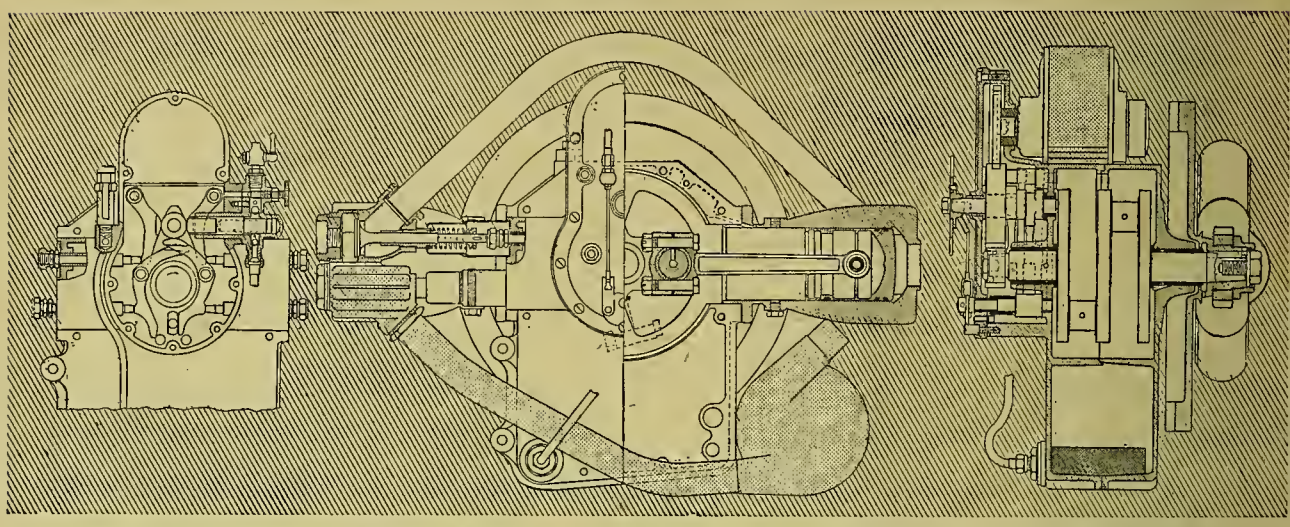
THE inventor of the Fletcher sparking plug radiators takes exception to my remarks on the unsuitability of his lower radiator for use on engines which have clearance only for a midget plug under the middle tube of the frame. As soon as materials are available in quantities, he hopes to market several styles of radiator, adaptable to any engine or any plug. It is, however, true that his sample radiator, as submitted to me, is inapplicable to engines which can only take a midget plug, and have no clearance for a tube spanner to be slipped over the plug. A King Dick can be used on a standard plug, as its hexagon barrel will protrude above the dished fins of the radiator. The Fletcher patents cover the application of detachable radiators to valve caps, compression taps, and compression release valves, as well as to sparking plugs.

Post-war Petrol Taps.

IN a recent issue I said some hard things about petrol taps, which have been a nuisance to motor cyclists for years past. They have almost always leaked, and their tapered plugs are apt to jam or seize in the seating. It was rather shortsighted of me not to realise that the immense dangers of petrol leakages on airships, aeroplanes, and motor boats were bound to lead to improvements, and I have just received a sample of a post-war tap. I must not describe it in detail for the present, but I may say that it has a flat circular seating, as large as a shilling, and faced with a special material. When tightened up so firmly that leakages are impossible, the tap opens and shuts as if it were on ball bearings. It is obviously an immense improvement on the old styles; if it has a drawback, it is that the petrol has to pass through two right-angled bends, so that any obstruction must be cleared by taking the tap to pieces, seeing that a wire cannot be pushed through it. However, if makers give us a smooth working tap which does not leak, it will be up to us to see that no dirt enters from the tank, and gauzes under the filler cap should ensure that.

THE MATCHLESS FLAT TWIN ENGINE.

Some Observations on the Mechanical Details. Aluminium Alloy Pistons Successlully Used.



MECHANICAL DETAILS OF THE MATCHLESS 5-6 h.p. FLAT TWIN ENGINE, 70 mm. × 95 mm. = 732 c.c.

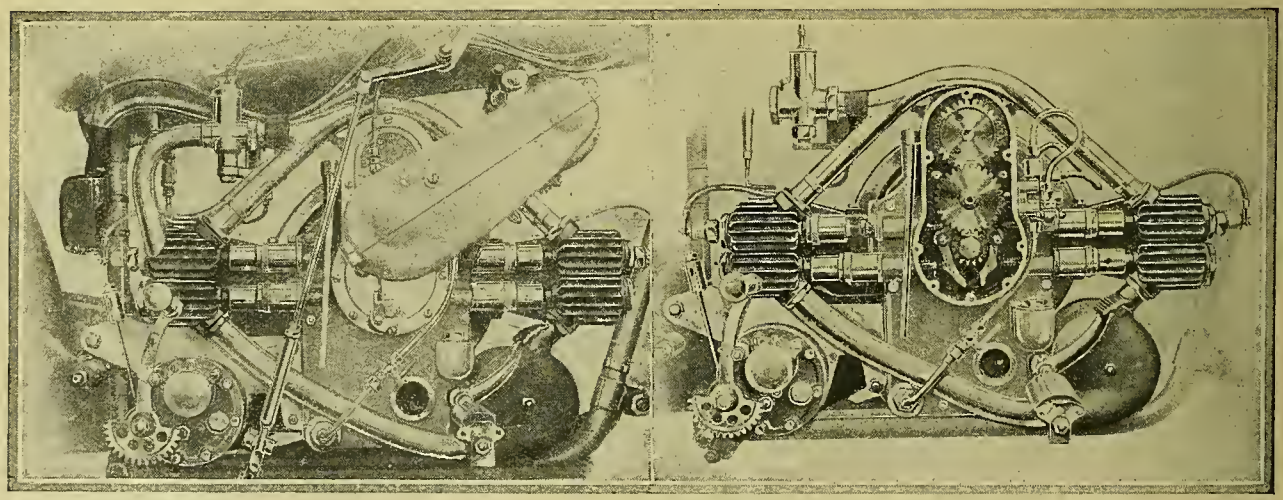
(1) Arrangement of valve gear, and cam operation of lubricating pump.

(2) Part section and side elevation of the engine.

(3) Vertical section on centre line, showing magneto drive and oil sump.

IN the issue of *The Motor Cycle* for November 16th, 1915, we published a full description of the new Matchless sidecar combination, and as the power unit is a distinct departure for this firm a few observations on the mechanical details and minor points of design will undoubtedly be of interest to our readers. The bore and stroke of this new engine are 70 × 95 mm. = 732 c.c., and the makers' rating 5-6 h.p.

One of the latest innovations is the adoption of aluminium alloy pistons, which, so far, Messrs. Collier and Sons, Ltd., have found to be most successful. These pistons are provided with two rings, and in the skirt a scraper ring is fitted, which allows increased oil pressure to be used without the accompanying disadvantage of oiled plugs. Each piston weighs only 18½ oz., including the rings, and is longer than the pistons usually employed in motor cycle practice, being 3⅜in. in length with a bore of 2¾in. This unusual length of piston is found necessary when aluminium alloy is used. There are six ribs underneath the head and an annular rib joining the two bosses taking the gudgeon pin, the object being to strengthen the piston, to radiate the heat from the piston head, and to preserve its truth by preventing distortion.



Timing gear side of the new 5-6 h.p. flat twin Matchless. Observe carburetter hot air collector, and position of dynamo and its enclosed drive.

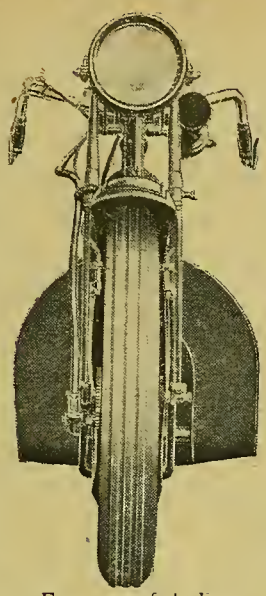
The engine with magneto drive and timing gear cover removed. The oil inspection window and also the feed pipe from the sump are discernible.

The Matchless Flat Twin Engine.

The connecting rods are somewhat short, being 7in. in length, this having been found necessary to keep the horizontal twin engine within reasonable dimensions.

The compression, though not abnormally low, is somewhat less in the case of this engine than in average touring types. All bearings are plain, as it has been found that with the forced system of lubrication ball bearings, which are usually adopted in flat twins to overcome the difficulty of lubricating, are not necessary.

The idea of fitting overhead valves was given up, as it was found that this would have involved an engine of too great a length, and the present system is more convenient. As regards the valve gear, experiments are being made with fibre timing wheels, a special kind of fibre, which is claimed to withstand both heat and oil, being employed. The valve guides of case-hardened steel are forced into the cylinders, and have the advantage of possessing excellent wearing qualities.



Front view of the latest Matchless, showing the sensible leg shields, which are extended under the engine and gear box, as shown in the lower illustration.

The Lubrication System.

To revert to the lubrication system, it was found desirable to fit a large sized pump, the surplus being returned by a by-pass, as a smaller pump, though large enough to carry out its duties effectively when the engine was warm, would not act efficiently when the oil was thick and cold. The present plunger feeds the lubricant well at all speeds. The main bush is provided with an annular groove and a passage leading direct into the flywheel boss, so that any excess of oil is carried *via* this passage to the chain case. There is a plug on the cylinder head, the same size as the valve caps, through which the engine may be decarbonised. This appears to be an excellent feature.

Provision for Cooling.

A large space is left between the cylinder and valve ports, while the longitudinal fins are excellently finished, and are a fine example of founders' work.

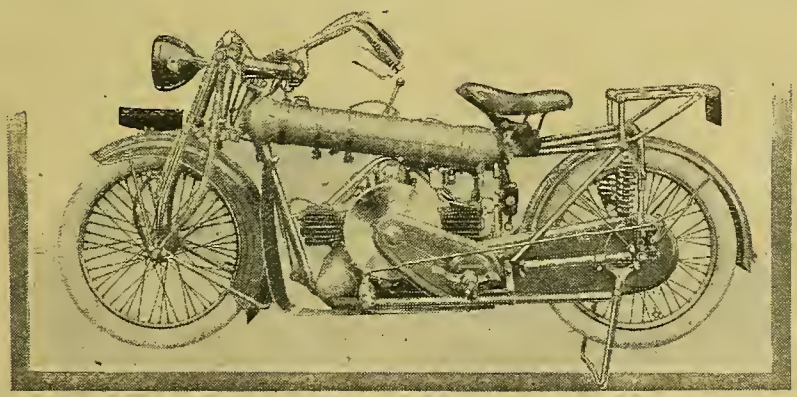
In the latter design the bosses for the compression taps have been discarded, as it has been found that the engine never gums up, and an injection of petrol is quite unnecessary. Owing to the excellently balanced flywheel and engine throughout, no transmission shock absorber is considered necessary. Messrs. Collier and Sons have found that in practice the side-by-side valve engine is smoother running than an engine fitted with overhead valves.

Valve Covers.

The accompanying drawings give a clear idea of the general construction of the unit, showing one of the valves in section, and over the other the valve spring protector, which is of telescopic pattern. A good idea of the long piston can also be obtained, as well as the shape of the radiating fins. The vertical section of the engine shows some interesting features of the lubrication system; for example, the size of the oil sump, the gauze at the base thereof through which the oil is drawn, the oilways cut in the main bearings, and the space referred to showing how the excess of oil from the right-hand bush is led into the recess on the flywheel boss, allowing the oil to leak into the chain case.

Interesting Cam Design.

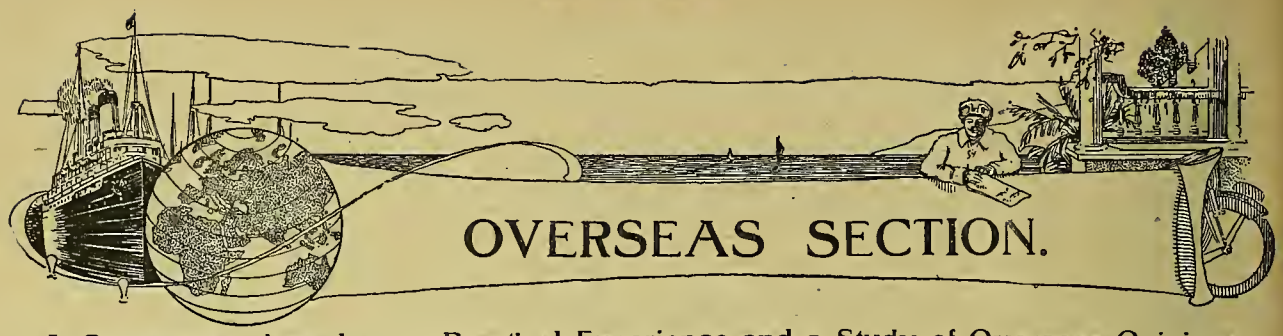
The drawing of the timing gear is also interesting, showing the single cam actuating one exhaust and two inlet valves, and the cam-actuated plunger pump, together with the by-pass. Between the two exhaust levers is a separate cam, which is employed for lifting the exhaust valves. The Matchless flat twin is certainly an engine possessing novelty and originality, and we hope, and expect, to hear a great deal more to its credit in the near future.



The newly-designed 5-6 h.p. Matchless, which has a three-speed countershaft gear box and transmission by totally enclosed chains.

Piston Ring Pressure.

A WRITER recently stated in *The Automobile Engineer* that he had investigated with a 3½ h.p. engine the pressures exerted on the cylinder walls by the piston rings. The original rings of the engine used exerted a pressure in the test of normally 11 lb. per square inch. For experiment he substituted a weaker set giving a pressure of 8 lb. per square inch, with the result that an increase of five miles an hour road speed was obtained. Tests of this sort, though exceedingly interesting, need to be of a very exhaustive nature if useful information is to be obtained from them, and the question of piston ring pressures is undoubtedly one of sufficient importance to warrant full investigation.



OVERSEAS SECTION.

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

IT is somewhat surprising that Overseas riders have not taken more favourably to the lightweight. Members of *The Motor Cycle* staff are not without fairly wide experience of riding conditions in pioneer lands, and our opinion on this subject was endorsed a few days ago by a Colonial rider who has figured in many endurance tests in Australia and elsewhere. His opinion and ours is that the fitness of the lightweight is not sufficiently realised by the majority of Overseas riders, and that the firmly rooted idea that weight and power are necessary for pioneer roads is more or less erroneous.

Almost every Overseas rider is familiar with the tiring work of handling a heavy solo mount on really bad roads, where it is very often necessary to walk, run, or push. When in the saddle the physical strain of holding up a heavy machine on deep mud or over ruts is really very considerable, whereas it requires very little effort to hold up a lightweight amidst the most trying conditions.

Where Revision is Necessary.

Generally speaking, the modern lightweight is as well off for power at low speeds as the heavy twin—that is to say, it will go anywhere the twin will go. On account of its lightness it is nothing like so susceptible to wheel spin, side-slip, etc., and consequently is just as able on gradients. As regards speed it is no great guns, but on bad roads this is of no consequence, while on ordinary mediocre going there is little in it.

Many present-day lightweights fall short of Overseas requirements on various points of construction and design, but this by no means condemns the class. Others are as sturdily built and just as capable of standing rough usage as the best heavyweight. During the lightweight revival it is to be feared that the tendency was towards the production of a cheap machine, and it is difficult to say even yet whether any real degree of permanency has been attained. Stronger front forks with more efficient springing, heavier wheels, greater efficiency in mudguarding, and more substantial mudguard attachments are points which generally need revision, while it goes without saying that nothing will be more influential in establishing the universal popularity of the lightweight than some efficient system of rear springing.

JUDGMENT IN PURCHASE.

REGULARLY we receive letters from Overseas readers asking for advice on the subject of purchase, but it is impossible to answer such enquiries in a helpful way unless we happen to have some knowledge as to the local conditions concerned A small flat twin, for instance, or even a baby two-stroke, may give perfect satisfaction to a reader at B, but at C, only forty miles distant, anything short of a chain-driven twin would be practically useless.

So much is obvious on the face of things, and in the construction of the ideal Overseas mount no fixed rules can be laid down with regard to size of engine, type of transmission, and so on, as many readers attempt to do. Each type of machine is good in its own particular sphere, and, bearing in mind that the novice and prospective purchaser is ever with us, we cannot ram home too firmly the advice—if you have any choice in the matter, study the various types of machine and decide what power and transmission is most suitable for your locality. Half the grumbles we receive are the result of injudicious choice, not to any actual shortcomings in the machines.

Here we have a very prominent reason for American success Overseas. In England numerous types and powers of motor cycles are produced, while in America, practically speaking, only one type is generally recognised. It is undoubtedly a good type for use in pioneer lands, but it is unanimously agreed that for superlative workmanship and durability there is nothing to equal the British production. And why we so often hear the British machine unfavourably compared with the American is because the Overseas buyer, determined to make a patriotic purchase, has before him a selection of types, and is likely to buy quite the wrong machine for his work.

The Bran Pie of British Productions.

Let this point be clearly understood. The American is built in a land of rough roads and great distances, and it is more or less standard as to type. Large, low compression engines and a positive drive are recognised as the general thing, whereas in England it is difficult to point out two machines among the 250 different models produced that do not differ considerably in some vital point, and it sometimes requires skilled judgment to decide which design is best suited to one's individual requirements. Even in England, where local conditions do not prevail to any extent, we realise the likelihood of obtaining possession of a machine which may fall short of our own personal requirements, and so the Overseas purchaser, though he has not the range of choice before him that we have at home, is more likely to go wrong when he plunges his hand into the bran pie of British productions than if he grasps the tin soldier from the well-illuminated shelf of the American sale stall.

There is, of course, no denying the fact that a few British machines are quite unsuitable for use in

Overseas Section.—

pioneer lands, but it must be borne in mind that in 1914 the vast possibilities of Overseas markets were only just becoming realised, since when the numerous lessons of the war have been taken to heart in a manner which would never have been brought about by a decade of Overseas grumbles. To-day the British motor cycle industry is fully alive to the fact that when peace conditions return every effort must be made to expand Overseas sales, and this can only be done by proper supervision of sales departments and by offering suitable machines. That many leading makers are giving Overseas requirements their serious consideration we are convinced, and there is no doubt that the outcome of present day experience in the way of building machines to stand every degree of rough usage will settle all question as to the durability of foreign competition.

THE INFLUENCE OF ENVIRONMENT.

IT will be recalled by many of our readers that at the outbreak of war *The Motor Cycle* was making plans for the organisation of an Overseas trial—that is, a trial over a freak route in the British Isles, as nearly representing pioneer conditions as possible. The idea was greeted with some enthusiasm, and the event promised to be one of the greatest interest and usefulness—so much so, indeed, that, when peace returns, a trial of this sort will probably become a standing item on the annual programme. With manufacturers fully alive to the importance of Overseas markets, and with one or two American or Colonial riders accustomed to rough roads to toe the line with the rest, there is no doubt whatever that such a trial would be very keenly contested, and prove instructive to all concerned.

The war, however, is providing a trial of a more searching nature than could ever have been brought about by the ordinary course of events, and its general effect will be towards producing an ideal machine for Overseas use. The unrelenting test of two years of the most strenuous usage to which a machine could be put has proved defects in construction and design which few manufacturers realised, and, moreover, the men who are now using machines at the Front will, on returning home, make much the same demands as the Overseas rider has made hitherto. We have learnt more during the war as regards strength of construction and durability than could possibly have been taught us in many years of ordinary progress, and the sum of the experience gained will all be to the advantage of the Overseas rider.

Bad Roads in England.

It must not be imagined, however, that the testing of British motor cycles is normally limited to the broad highways, for in many parts of England are to be found lanes and mountain tracks which compare favourably with the average bullock cart road, and many manufacturers are in the habit of testing their machines over these freak routes—deep heather, peat swamps, boulders, and rivers being the common order. Amidst such surroundings much has been learnt as regards sidecar attachment, gear ratios, clutch efficiency, engine cooling, etc.

A Selection of Letters from Readers scattered all over the World.

OVERSEAS LETTERS.

AS usual, we append a few Overseas opinions gleaned from our letter-box. Unfortunately space does not permit our using many of the suggestive and interesting letters we receive from Overseas readers, but their non-appearance must in no way be taken as a reflection on their interest or usefulness.

American Machines Again.

MR. CRACKEN, Calcutta, India: "As soon as a shipload of American motor cycles arrives they are all sold out in a few weeks. I regret this state of affairs very much, but if the English manufacturer will stick to his old ideas of chain-cum-belt, small wheels, and high prices, then he must go to the wall. It is all very fine to be patriotic; at the same time we want value for our money, and in this respect the American twin undoubtedly leads."

Three Tracks Undesirable.

MR. HART K. BENNETT, Volksrust, Transvaal: "We have several regular readers of *The Motor Cycle* in Volksrust, and look forward to its arrival. One of the pleasing points we look for is the illustrations of improvements to machines. In regard to the Scott Sociable, the two-wheel track is preferable to the three-wheel track out here, for often on the country roads the centres are from 6in. to 12in. higher than the wheel tracks, and therefore unsuitable for three-wheel track machines. Motor cycle makers should give greater clearance for machines exported to South Africa."

Buying a Machine in Australia.

MR. F. E. SMITH, Toowoomba, Queensland, Australia: "Why is it that while British manufacturers are spending money on advertising their machines and accessories they do not at the same time advertise the names of their foreign agents? I have enquired for two or three machines, the merits of which I should have liked to go into, but have in each case been unable to find out whether these are stocked in Australia, while American machines were to be found without the slightest trouble. I might remark at the same time that having only an agent in Melbourne is about as much good to a Queenslander as having an agent in, say, Marseilles would be to a buyer in London."

A Satisfactory Two-stroke.

MR. E. G. HOWARD, Adelaide, South Australia: "I have been much interested in your correspondents' experiences with two-strokes, and perhaps mine at this end of the globe may be interesting to your readers. I have been the possessor of a Baby Triumph for over a year now, and all the symptoms described in your paper are entirely absent with my machine. I have never had the mysterious rattle; it never four-strokes, even at the slowest speeds; and, contrary to 'Ixion's' experiences, it always fires regularly starting from cold, no matter how long standing. It will take me over the Mount Lofty Range on top gear with the exception of one pinch, which is 'some' climbing. Whether the condition of the atmosphere out here accounts for it I do not know. Certainly I look well after it and keep the cylinder clean. The engine shows no sign of wear yet. The disclaimer is not necessary at this distance."

The Overseas Summary.

"SOUTHERN CROSS," Farnborough, Hants: "I have read with very great interest your 'Summary of a Year's Correspondence on the Overseas Motor Cycle' in your issue of January 4th.

"Having recently arrived 'home' (on special leave for war work) from New Zealand, where I have been connected for a number of years with the motor branch of a large Government department, may I congratulate you on the manner in which you have summarised and shown several of the defects which should be overcome in machines intended for Colonial use?

"If British manufacturers and their agents would only take as a motto what your Australian reader so expressively puts, 'American standards of service plus British standard in quality of goods,' the Colonial market is assured for their products.

Overseas Section.—

"There is little in your summary that can be criticised, and I can fully endorse most of the points you have brought out. We have found that for the heavier class of machine the all-chain drive with countershaft clutch stands up the best, but invariably the rear chain cases and original mudguards are cast away. The chain cases are generally replaced by a strip of steel plate which acts as a stoneguard, and mudguards of a wider section, heavier gauge, and with stronger stays, are fitted. The shallow ground clearance of engines, silencers, and exhaust pipes (and magnetos on some makes) must be remedied. One manufacturer has already increased the clearance on a new model in these respects, and larger capacity tanks, tool bags, etc., are also apparently having attention.

"Engine capacity is, as you state, an open question, and we have cycles with engines ranging from 2¾ h.p. to 8 h.p., each efficient in its own particular sphere of action.

"We have found that, where machines are in constant use in all conditions of weather and roads, black is the most serviceable colour.

"Commercial sidecar frames need considerable improvement both in design and material; some models we have had to rebuild throughout.

"I hope that these few lines may assist you to drive home the fact that British manufacturers must get away from a system of 'tai-hoa' (the South Sea Islander's expression akin to 'wait and see'), if they purpose keeping the large markets of Australia. Opposition is made more severe by the opening of the Panama Canal, facilitating shipping from the U.S.A., as well as helping to maintain 'American standard of service.'

"Wishing your paper the continued success which it deserves."

American Comparisons.

Mr. C. H. Mann, India: "I notice in your 'Overseas Opinions' in some of your recent issues, that several correspondents are rather bemoaning the fact that certain American motor cycles are ousting English makes. This is certainly a fact that is to be deplored; but, after all, riders in the Colonies must study their own comfort, and if British makers will not construct a practical machine for Colonial use and roads (?) then the American firms will get the orders.

"Look at the advantages of, say, the American 7 h.p. machines over any single British-made one: (1) Cradle spring frame; (2) 28in. × 3in. strong and heavy tyres; (3) mechanical oil pump; (4) very good clutches and plates, which will stand a lot of wear; (5) a good three-speed gear box, compact and strong; (6) last, but not least, the chain drive—an absolute necessity in the 'rains' out here. Most people here have a sidecar, partly to carry things and partly to steady the bicycle, so that if coolies deliberately wander and do 'tangoes' just in front of your bicycle there is a chance of your not coming off the machine (they frequently do this, by the way). The heavy 7 h.p. Indian is splendid with a sidecar and holds the road well. The laminated spring frame just rocks one over holes, etc., and is far superior to spiral springing, which recoils too quickly."

The American Invasion.

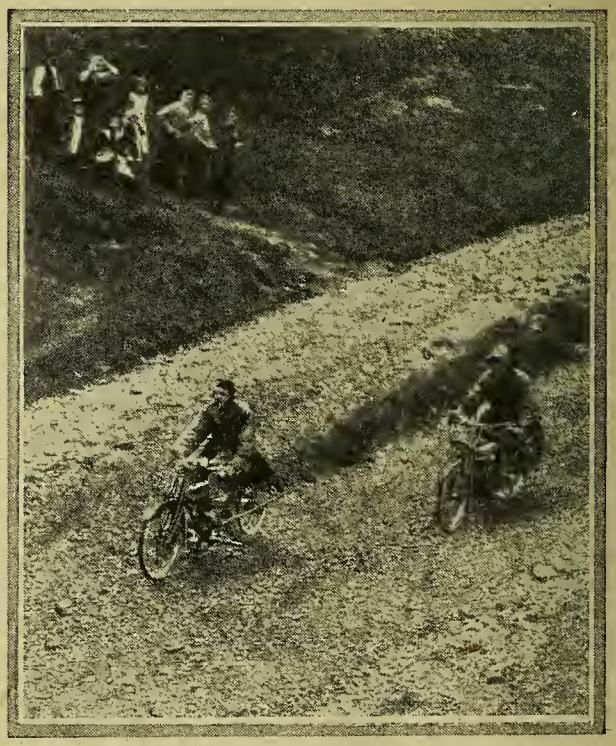
Mr. A. C. Trevor, Adelaide, South Australia: "I take the opportunity of your 'Letters from Overseas Readers' section of your excellent paper to warn you, as many others have warned before me, that the English motor cycle market is dwindling rapidly, and will almost disappear soon if the British manufacturer does not wake up to the realisation of the enormous hold America is getting on the trade. The reason for this preference for U.S.A. motor cycles out here is obvious, in that they are the machines best suited for standing the Australian road and climatic conditions. Far be it from me to decry the English power unit, which is, in most cases, a beautiful piece of work, and is represented out here to the largest extent by the J.A.P. As a matter of fact, the following remark made while looking at a powerful American is often heard: 'Put an 8 h.p. J.A.P. in that frame and you have the perfect machine.' My remarks are made chiefly in regard to the English builders' almost complete lack of interest in the big twin, and his apparent inability to see that a spring frame in these parts is becoming almost a necessity. Of course, we all agree that the A.J.S., Clyno, and a few other sidecar machines are probably all that could be desired on the roads of the Old Country; but in this country they are undoubtedly uncomfortable. There are two or three of the American features that I consider it would pay to adopt, namely, the excellent system of twist grip control, larger and more efficient brakes, 28in. wheels, 3in. tyres, and last, but not least, a spring frame of some description. If an English cycle of about 8 h.p. embodying the above features could be sold out here for about £90 (the average price of big American twins) instead of £110-£115 it would become very popular."

The Simple Single.

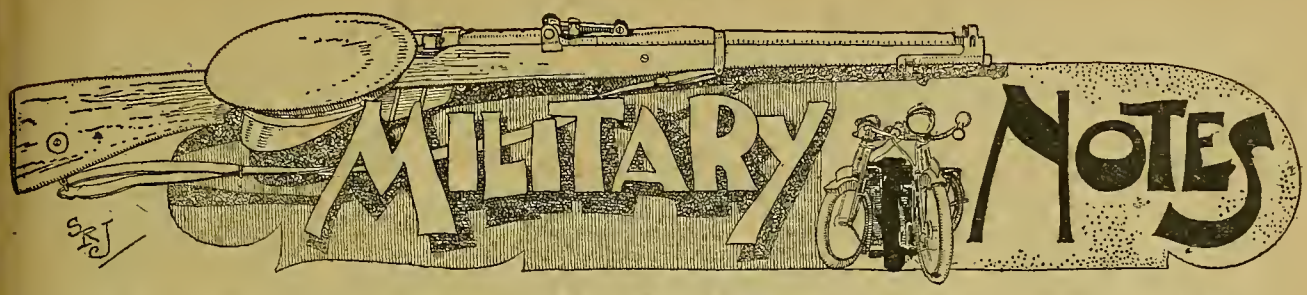
Mr. W. Pointer, Fort Beaufort, C.P., South Africa: "I have ridden a 5-6 h.p. Rudge Multi single-cylinder for the past few years in a hilly district of the Cape Colony. The full power of this engine has never been required, therefore I fail to see the necessity for more cylinders, with their corresponding extra complication, expense, etc. The only drawback to a single-cylinder is the fact that one's mechanical knowledge is apt to get rusty, its reliability being so absolutely monotonous. In the year 1900 I rode a single-cylinder De Dion tricycle. I had no mechanical knowledge, but, in spite of this fact, I never once got stranded. 'Ixion' compares the comfort of twin and single-cylinders; in my opinion, both are free enough from vibration at normal speeds."

More Grumbles.

Mr. J. S. Watson, Dudley, N.S.W.: "I suppose you are about tired of hearing Australian motor cyclists grumbling about cost of renewals and spares for British-built machines. One thing I would be pleased to see explained: A rider of an Indian can (I am told) buy his spares and renewals in Sydney at a very small advance on what he would pay in New York. I use an English machine. In Sydney I am charged for renewals at the rate of 200 to 250% advance on English list prices! Please don't blame this on the war. Agents were charging just as much prior to the war. I do not think we shall see any change for the better until the big British makers establish their own depôts out here."



It is not difficult to find roads in England which vie with colonial conditions of surface. These "roads" are in many cases used by British manufacturers as test ground for Overseas models.



"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS "TANKS."

WELL KNOWN TO MOTOR MACHINE GUNNERS.

AMONG the officers and men brought to the notice of the Secretary of State for War for distinguished services rendered in connection with the war, is Lt.-Col. R. W. Bradley, D.S.O., South Wales Borderers and M.G.C., formerly Commanding Officer of the Motor Machine Gun Training Centre at Bisley Camp.

HONOURS FOR MOTOR CYCLIST AIRMAN.

THAT dashing motor cyclist, Capt. John Woodacre Woodhouse, of the Royal Flying Corps, has been awarded a bar to his Military Cross. Woodhouse will be recalled as a frequent competitor in Tourist Trophy races and motor cycle reliability trials of the past. His Military Cross was obtained for gallant conduct on the Western Front. Capt. Woodhouse is at present stationed in England. A further distinction for Capt. Woodhouse was the inclusion of his name in the War Office list, dated January 25th, of officers and men mentioned for distinguished war services.

SKILLED RECRUITS WANTED.

YOUTHS of eighteen years of age who have passed through an apprenticeship in one or other of the skilled engineering trades, but are not fully occupied on war work in the shipyards or munition factories, may report to their recruiting officer, and request to be trade-tested, passing as artificers. There are vacancies for such lads in the Royal Engineers, Royal Flying Corps, Army Service Corps, and Machine Gun Corps, Heavy Section (Tanks), and also in the Royal Regiment of Artillery and the Army Ordnance Corps.

TESTING WAR OFFICE MOTOR CYCLES.

HITHERTO the P. and M. motor cycles manufactured for the Royal Flying Corps have always been subjected to a very severe test on Brooklands Track, and accounts of the tests have appeared in these columns in the past. Owing to the unfailing regularity with which the machines have fulfilled this test, the Ministry of Munitions has decided that the tests are no longer necessary, and they are therefore being discontinued. The whole of the P. and M. production is, of course, still being delivered to the Government.

SIDECAR AMBULANCES IN FRANCE.

AT the present time the British Ambulance Committee, attached to the Service de Santé Militaire, 23a, Bruton Street, London, W., have no fewer than five convoys of motor or ambulance cars, together with a motor cyclist stretcher car section, working with the French forces at vital points between the Somme and the Vosges.

The expenses of maintenance and upkeep are heavy, and, apart from the administration charges, vehicles destroyed by enemy fire and those used up by the wear and tear of active service must be renewed.

It is to the general public that the promoters look for the necessary funds to enable them to carry on their good work. From time to time vacancies occur for capable volunteer drivers. Particulars of service can be obtained from, and subscriptions may be sent to, the headquarters in London.

PROMOTION FOR A.C.U. TRIALS JUDGE.

WE note with pleasure that Maj. A. E. Davidson, D.S.O., R.E., Assistant Director of Mechanical Transport, graded for pay as A.Q.M.G., is to be a temporary lieutenant-colonel while so employed.

Col. Davidson is well known to a large number of motor cyclists, as he acted as judge in numerous A.C.U. trials and competitions.

Lt.-Col. Davidson, D.S.O., R.E.

For many years Col. Davidson has been associated with mechanical transport for the Army, and before the motor transport section of the A.S.C. was established he was one of the secretaries of the Mechanical Transport Committee of the War Office.

He served in the South African war, and was in charge of the only form of mechanical transport then in force, namely, the traction engine. Later on he became a keen devotee of the internal combustion engine, and made a careful study of the motor bicycle employed for military purposes. He was largely responsible for the Army being supplied with motor bicycles at the outbreak of war.

MORE GOVERNMENT MOTOR CYCLES.

THE Enfield Cycle Co., Ltd., Redditch, has just received through the Ministry of Munitions a further large order for 6 h.p. and 8 h.p. Royal Enfield motor cycles. Enfield sidecars were among the earliest equipment of the Motor Machine Gun Service, and for many months past have rendered magnificent service in France.

A WELL-KNOWN MOTOR MOUNTAINEER CLIMBS HIGHER.

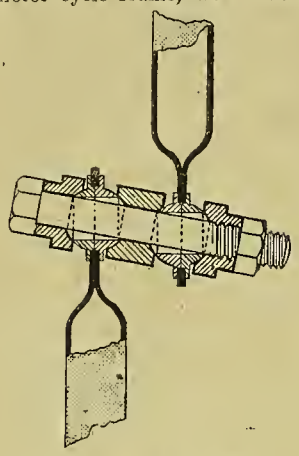
AMONGST the officers mentioned by Field Marshal Sir Douglas Haig in his New Year despatches is the name of Maj. W. B. Little, so well known in the happy hill hunting days, when Helvellyn, Skiddaw, and many northern mountains were climbed. The name is familiar also to innumerable trials riders. Little's promotion has been remarkable. When last mentioned in *The Motor Cycle* he had been appointed Staff Captain with the Durham Light Infantry in the 151st Brigade. Last autumn, after earlier having received the Military Cross, he was taken from Territorial rank, and became a captain in the Regular Army. Since then hard fighting has been experienced under severe conditions in the trenches, mainly with the Border Regiments. Maj. W. B. Little, the genial friend of many a motor sportsman, is much beloved by the men of the 5th Border Regt., who are at present under his command.

In his latest letter he modestly tells of a narrow escape which befell his party. He writes: "Snow and frost! The cold is intense. We are where the shells fall thickest; in fact, a few minutes ago a 'blighter' knocked in the end of our dug-out, and we are just trying to get it cleared. It was also a narrow shave a few days ago, when along with my orderly I was buried by the 'exhaust' of half a dozen shells which landed a few yards from us." His numerous friends will wish Maj. W. B. Little similar good luck in the future.

A NOVEL FRAME CONSTRUCTION.

Mr. Alfred A. Scott's latest Patent of a Triangulated Frame Design embodying Interchangeable Tube Members.

MR. ALFRED A. SCOTT is one of the few inventors whose productions never in any way appear to be disturbed by the conventional order of things, and when, some months ago, we heard that he was busy on an entirely new motor cycle frame, we immediately



Nut and bolt fixing, showing the domes and spherical washers which allow for the angular position of the tubes.

anticipated something out of the ordinary. Now that we have had full opportunity of examining this latest invention and discussing its possibilities with its ingenious inventor, we are by no means disappointed, and though the frame as yet remains to be tried on the road, it will be recalled that the Scott Sociable, which we have already described and tested, embodies a somewhat similar principle as regards frame construction.

The primary aims of Mr. Scott in designing his new motor cycle frame were:

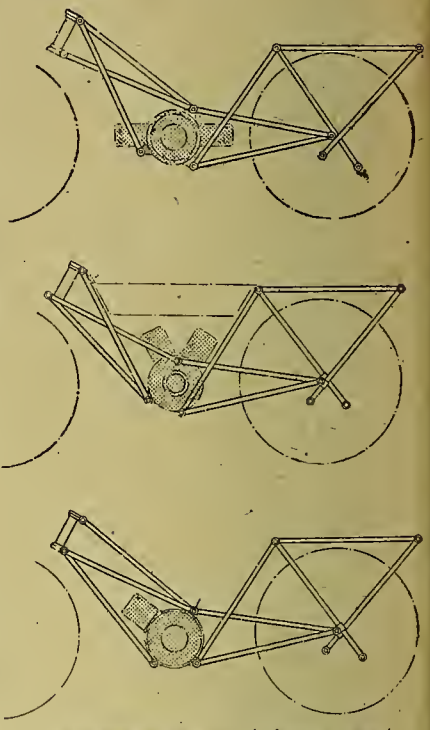
1. To eliminate bending and twisting strain in the members.
2. So to construct the framework that in case of an accident any damaged member occupying an important position can be withdrawn from the frame and instantly replaced, either by some member occupying a less important position in the structure, or by a spare tube length.
3. To evolve a frame which consists of a number of identical and standard tube lengths, which on reference to a plan can be assembled into a complete frame without brazing or other heat treatment.
4. To reduce weight and cost of production.
5. To obtain maximum strength by the employment of interconnected triangular structures built up round the engine, which forms the base or foundation of the framework.

Interchangeable Frame Members.

In this invention Mr. Scott has an entirely open field before him, and, as will be seen from our drawings (which show the new frame adapted to various types of engines, including the flat twin), the structure consists of a number of eye-headed standard tube lengths, the end of each tube being flattened and punched so as to form an eyepiece. In place of brazed junction lugs, nut and bolt fixings are used throughout the frame, but it is clear that, to allow for the necessary angular position of the various members, some adaptable mode of fixing was necessary.

Nut and Bolt Fixings.

The arrangement adopted is clearly shown in one of our sketches. The aperture of the eyelets on each side are domed spherically, while spherically recessed washers, or packing pieces, are placed over the bolt, one on either side of the dome. The eyelets are somewhat larger than the bolt, so that the nut can be drawn up tightly with the members in any angular position within limits.



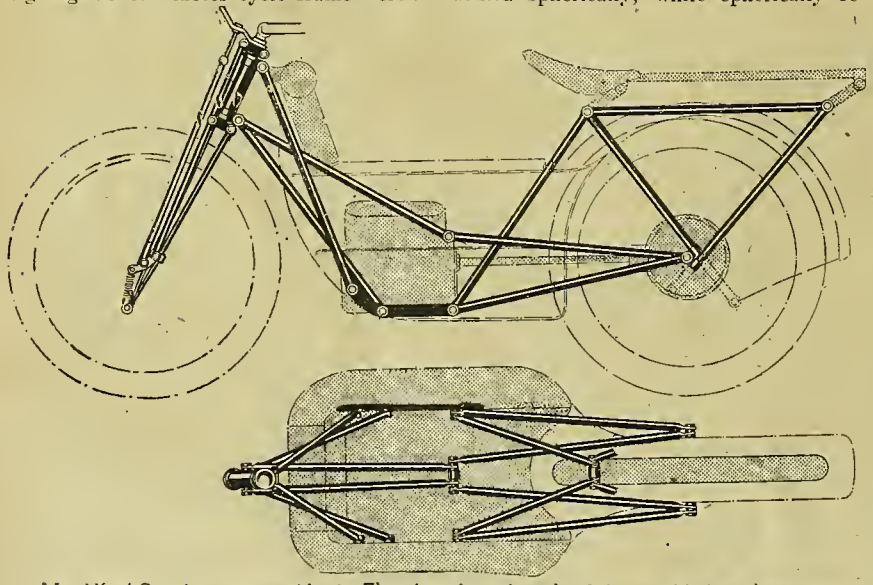
Three alternative frame designs, arranged to accommodate respectively flat twin, V-type, or inclined engines.

The Fundamental Principle.

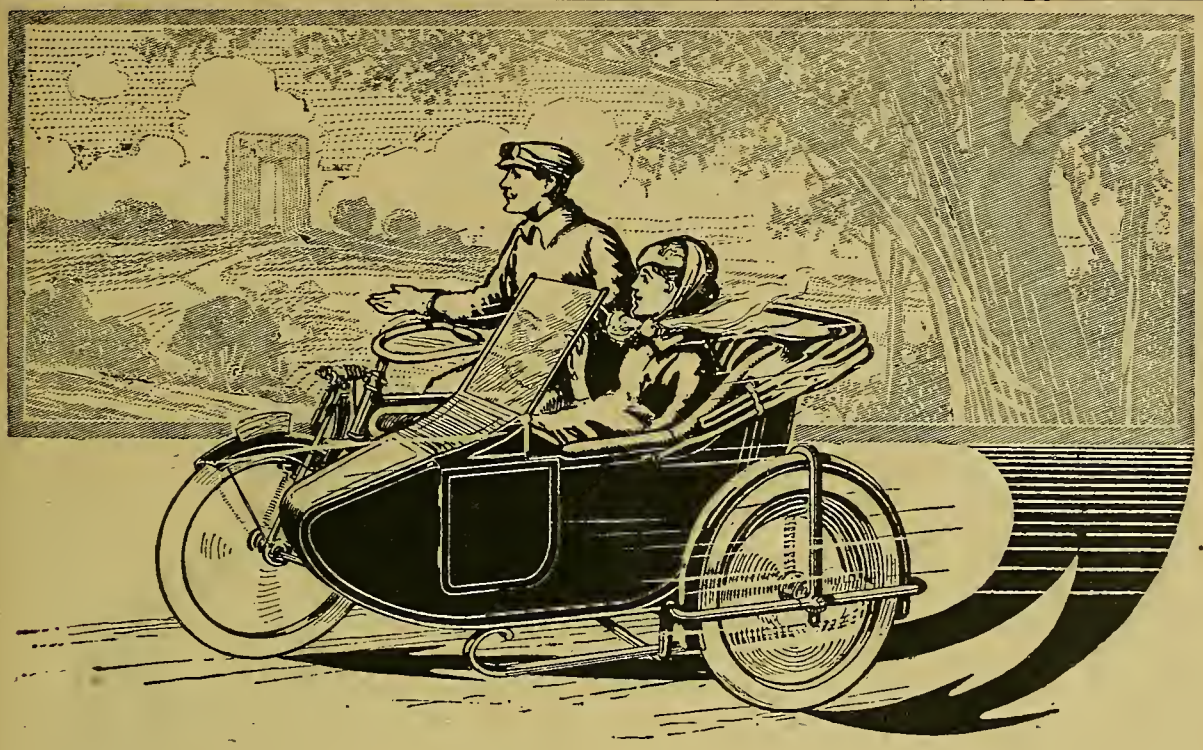
A glance at the frames illustrated conveys some idea as to the engineering skill which has been brought to bear on their design. It will also be noted how readily this type of frame adapts itself to any form of power unit. The engine in every case forms the foundation of a triangular structure, while the steering head forms a similar base, all stresses being met by straight tubes, which are subjected to no bending strains whatever. The elimination of all intermediate stresses renders possible the employment of much lighter gauge tubes than it would be safe to use in a structure of unmechanical design. The frame is triangular in every direction, that is, whether viewed in plan or side elevation—so that in whatever direction the strains fall they are met by interconnected and interchangeable struts, which are subjected only to direct tension or compression.

Vertical Rigidity.

To restrain any tendency on the part of the steering head to oscillate, members are carried from a point high up on the steering head to the respective sides of the engine base, while similarly two members pass from the seat down to the engine base, thus forming the seat apex, and tending to resist torque stresses.



Mr. Alfred Scott's very latest idea! Elevation of a triangulated frame with interchangeable tubing. The saddle is mounted on parallel links and the carrier is sprung in unison.



¶ The one economical factor left in motoring to-day — the one cheerful feature of the motor cyclist's landscape—is Avon Endurance. In war, as in peace, Avons fight the battle of the road with the single aim to "get you there" at least trouble and lowest cost.

¶ Prices substantially reduced since War commenced, but the same fine range of weights to select from.

OF ALL CYCLE AND MOTOR CYCLE AGENTS.

Saddle Height Adjustment.

The two saddle members extending from the seat to the rear wheel axle are attached at their lower extremity by means of clips, which act as a medium whereby the saddle height is adjusted. So far as is possible the front forks also are built up of standard tube lengths, the springing, as will be seen, being effected on a simple cantilever system.

In case of accident on the road which involves the breakage of an important frame member, the mishap would not necessarily strand the rider, since a less important member—say, for instance, one of the back carrier stays—could immediately be substituted for the broken tube, and the machine ridden thus till a new tube length had been obtained. The frame can be very speedily assembled, and errors in alignment, the avoiding of which require so much care and skill when brazed lugs are used, cannot readily occur. Frame breakages are generally due to the burning of a tube in brazing—a liability entirely eliminated in this design, which has no brazed junction lugs to weaken the frame.

The principle of this new departure in frame design is unquestionably one deserving the thought of automobile engineers, the advantages it offers, not only in the way of cheapness, lightness, and convenience, but also for compact shipment to foreign markets, being vitally important points.

FROM A BELGIAN ENTHUSIAST.

E. TAYMANS, secretary of the Brussels Motor Club, writing from Le Havre, says: "People abroad would never imagine the vile state of the roads upon which we are obliged to ride. In fact, they are no longer roads, but a succession of big pot-holes, some of them deep enough to drown a dog in. Moreover, the very poor quality of the lubricating oil issued to us tries the unhappy engines to the full. The way the James sidecar performs its task speaks well for this make of machine, the James being about the only sidecar machine in the Belgian Army. For solo riding we have all sorts of machines, most of them, happily, of British manufacture: Triumphs, Rudges, Humbers, Premiers, Royal Enfields, even an old 1905 4½ h.p. twin Minerva, which has been in service since the beginning of the war, and on which I personally covered over 3,500 miles in two months' time. Our main trouble is caused by mud running down the front forks into the hubs, which, though dismantled every week, wear out all too quickly.

"It is a pity manufacturers do not realise that the size of the tyres they fit are, generally speaking, much too small, for anything under 2½in. ruins the rims very quickly. In fact, the only really reliable tyres I had were the 760×90 voiturette (Ford) tyres which I fitted to my Indian instead of the 26×3in. usually fitted. They fit beautifully on the standard rims, and when run slightly deflated give very smooth running. Their long life repays their slightly higher cost. We usually fit 700×80 on all 650×65 (Rudge) rims, with much benefit to the comfort of rider as well as to the durability of the machine.

"On the whole, we are surprised at the way the motor cycles stand to their work in these appalling conditions. In peace time we used to grumble at the roads, but now—!! However, we keep enthusiastic about our hobby, and I for one hope the Germans will not have stolen the trusty T.T. racing Triumph which I used to ride in trials previous to the war.

"I wish you and your paper (which I have read since 1906) every success."

PETROL AFTER THE WAR.

A contemporary remarks that it would not be too much to hope that the Petrol Trust might receive attention in due course at the hands of the State. But the suggestion comes too late—*The Motor Cycle* in the issue of January 4th made a hint that the Government had already moved in the matter of the control of petrol supplies after the war.

E. Taymans, Motocycliste Militaire Belge, C.T.H. Le Havre, on a Premier, and his brother on a James. In some of the roads in the district, we are told, there are pot-holes big enough to hide a dog.

Average Prices of Second-hand Machines.

WE give below the average prices of second-hand models offered for sale in *The Motor Cycle*. Where it is possible to obtain a sufficient number of each model the average for the past week is quoted, otherwise the last average is given, if within four weeks. Difficulty in obtaining a sufficient number of one particular model often arises, owing to the fact that many advertisers omit some of the most essential details.

That Erring Compositor.

A trade contemporary refers to a *five*-speed Triumph having been seen on the road. Arguments in favour of four speeds we have had in plenty, but we recollect no rider of experience urging the desirability of *five* speeds. A misprint, no doubt.

Petrol Substitutes—the Solution.

Though petrol licences are not now available for those henceforward joining the ranks of motorists, it must be remembered that excellent substitutes for petrol still abound, and at figures more favourable than petrol. Thus there is nothing to prevent new converts taking up motor cycles if work can be performed more quickly and efficiently by their use.

Foreign Exports.

We are informed by the Commercial Intelligence Branch of the Board of Trade that in a supplement to the *Board of Trade Journal* of January 25th was given a complete list of articles which, according to the latest information received by the Board of Trade, are prohibited exportation to various destinations—from the Straits Settlements, Hong Kong, Nigeria, Gold Coast, Jamaica, Barbadoes, Trinidad and Tobago, and British Guiana. The Supplement can be obtained through any bookseller, or direct from His Majesty's Stationery Office, Imperial House, Kingsway, W.C.

Mr. Charles A. Hyde, the new president of the Cycle and Motor Cycle Manufacturers' and Traders' Union.

A Juvenile Dorando.

Recently a member of our staff was riding the Great North Road on a powerful twin when he discovered that his spare tube case had dropped off. Returning to look for it he found a very small boy cheerfuly pursuing him, the spare tube case in his hand. Apparently the youngster entertained lively hopes of overtaking the motor cyclist in the next mile or so!

Institution of Automobile Engineers.

At the fifth meeting of the session of the Institution of Automobile Engineers, to be held on the 14th of February in the Hall of the Royal Society of Arts, John Street, Adelphi, W.C., Mr. F. L. Martineau, M.I.Mech.E., will read a paper on "Hydraulic Transmission."

Cards of invitation may be obtained on application to the Secretary of the Institution, 28, Victoria Street, London, S.W.

We All Agree!

Our contemporary, *The Scottish Cyclist and Motor Cyclist*, refers to the fact that American writers are repudiating the invention of the term "flat" twin as a substitute for "horizontal" twin. "But what is there to repudiate?" enquires our Scottish contemporary. "Isn't 'flat' twin just as descriptive and useful as 'horizontal' twin, and a lot shorter to think, say, or write?"

Following upon the Irish opinion, stated last week, it is clear that the British Isles, at any rate, are agreed upon the term.

New Officers of the Manufacturers' Union.

At a Management Committee meeting of the Cycle and Motor Cycle Manufacturers' and Traders' Union, held in Coventry on January 23rd, the resignation of the president, Mr. Harry Smith (the Rover Co.), was received with regret. We understand that the reason for the resignation of Mr. Harry Smith is that the Rover Co. is no longer engaged in the manufacture of either cycles or motor cycles. Mr. S. Bettmann (vice-president) having also resigned, the committee were under the necessity of filling the vacancies until the next annual meeting. The only remaining vice-president, Mr. C. A. Hyde (Birmingham Small Arms), was therefore elevated to the presidency, while the two vice-presidents chosen were Mr. Bernard Steeley (Joseph Lucas, Ltd.) and Mr. J. R. Nisbet (Bowden Wire). A further change was made in the administrative staff, Mr. A. Bednell becoming general manager of the Union and Mr. Timerick secretary.

SPECIAL FEATURES:

INSTRUCTIVE OVERSEAS COMMENT.
A NOVEL FRAME CONSTRUCTION.
CAM DESIGN.

Fully Equipped!

In the current issue of a popular British magazine a gasoline launch is illustrated having a smoke funnel. Possibly the artist thought that gasoline was related to vaseline, and required a furnace to carburate it.

Returned to Civilian Life.

We are informed by the Ariel Works, Ltd., that they have obtained the services of Mr. J. W. Stocks as general manager of Components, Ltd., and Ariel Works, Ltd.

Mr. Stocks has long been a prominent figure in the motoring world. An old racing cyclist, holder of the World's Hour Record, and winner of the 100 Kilometres World's Championship, he was also one of the earliest members of the R.A.C., and one of the first motorists to race with Messrs. S. F. Edge and Charles Jarrott on the De Dion motor tricycle at the end of last century. Mr. Stocks also drove in the Gordon-Bennett Race of 1903, and for many years—in fact, right up to the outbreak of war—he made a practice of driving from London to the annual motor show in Scotland.

More Varied Experiences.

For six years, terminating in 1907, Mr. Stocks was general manager of De Dion Bouton, Ltd. He left England in June, 1915, for Gallipoli in charge of a Machine Gun Squadron, and, after rather a trying time, which included the Suvla Bay landing, he was wounded on October 18th, 1915.

Mr. J. W. Stocks, the new general manager of Components, Ltd., and Ariel Works, Ltd.

The Use of Cameras.

Nowadays a photographer has to go about his work very warily. Amateur photographers in particular run many risks in exposing a camera at all. One, for instance, was arrested the other day for photographing a man sweeping snow!

Proposed Association of Private Owners.

An adjourned meeting was held on January 16th, and, though the attendance was small, it was evident that feeling was in favour of the formation of an association. It was, however, recognised that, owing to the absence of so many small car owners and for other reasons, the moment is inopportune for launching the organisation, though it was agreed upon to form a small committee which, at its own expense, is to take into consideration the views of its members. The acting secretary, Major H. Vane Stow, 353, Strand, London, W.C., will be glad to receive views from those interested.

Coroner's Plea for More Lights.

Mr. Ingleby Oddie, the Lambeth coroner, on the inquest on the body of a man who was killed by a R.F.C. motor car on Sunday evening, January 21st, suggested that the lighting regulations had been carried too far. Everyone, he said, appreciated the necessity of darkening our streets, but he had never heard of Zeppelins arriving before nine o'clock in the evening. Between sundown and nine o'clock were the hours of greatest danger, for it was then that many people were hurrying home through darkened streets. It was a question, he added, whether the time had not come when full lights should be allowed—at any rate till 9.30.

The "Crush Four."

The people who made the regulations, said Mr. Oddie, perhaps did not travel by trams and omnibuses, and so did not realise what a terrible state of things existed in London during the "crush hours" at night. In his own district, during October, November, and December, 1913, there were seventeen inquests due to street accidents, while during the same months of 1916 there were forty-seven!

No one realises the difficulties and dangers referred to more fully than the motorist.

The R.A.C. a Government Office.

It was announced on Saturday that the Royal Automobile Club buildings would be taken over by the Government for use as offices. Several daily journals, which have not taken the trouble to enquire as to the immense help given to the nation by this institution, have urged that this step should be taken. It is not generally known that the R.A.C.'s organisation has been at the disposal of the War Office and the Ministry of Munitions since the war started, and much valuable—we might say invaluable—help has been given. The technical department has done useful work for the War Office, and the Club's engineer has devoted his attentions to the British Red Cross Society.

It is said that the decision as to the Government Department to which the immense building will be assigned is still in abeyance.

A Remarkable One Lunger.

A truly remarkable runabout is the subject of an article and illustrations in yesterday's issue of *The Light Car*. The machine has a 3½ h.p. air-cooled single-cylinder engine and belt transmission, and the weight is no more than the average sidecar combination. The body is built like a boat, and, what is more, it has a keel like a boat and no other frame; the body takes the driving strain, and the belt runs outside the body. This (bracketed with the Carden) is certainly the nearest approach to a motor cycle on four wheels.

A New Profession.

The latest addition to the records of crime is the stealing of London taxicabs. The cabs are stolen only in so far as they are removed from the idle rank by a man alleged to be wearing the uniform of the British Motor Cab Co.—often from under the very nose of their rightful drivers—and after being driven some miles by this enterprising gentleman they are left in a quiet side street—minus magneto! In this way the man acquired possession of four magnetos last week—one on Monday, two on Tuesday, and one on Wednesday—not bad going! He must be making quite a good thing out of it, and one wonders whether he will shortly switch on to omnibuses.

Blackpool National Motor Volunteers.

The Blackpool N.M.V. met last week to do honour to their commandant, Conn. A. Lindsay Parkinson, the Mayor of Blackpool, and their sub-commandant, Mr. J. Prestwich. Each of them was presented with a sword, a symbol of appreciation, by the N.C.O.'s and men of the services rendered to the command by the two officers. The interesting ceremony coincided with the announcement that the War Office had at length given recognition to the National Motor Volunteers.

Amendments to Lighting Order.

Amendments to the Lighting Order were issued on Tuesday morning, a number of towns on the south-east coast now being affected by Part III. as well as Part II. of the Order. The towns in which Part III. applies have now been reduced by the latest regulations to Colchester, Harwich, Dover, Folkestone, Hythe, Margate, Ramsgate, Sandgate Urban District, Felixstowe, Ipswich, and Walton Urban District.

Quaint Grounds for Exemption.

A Mansfield hosiery worker informed the local tribunal that he had discovered a new spirit which had been successfully tested on motors and which was likely to supplant petrol. The Ministry of Munitions was testing its efficiency, and he felt sure that the spirit would be of great value to the country. On these grounds he appealed for exemption, which was granted pending a reply from the Munitions Department as to the result of its tests.

Features of this Issue.

This week's issue of *The Motor Cycle* contains several exclusive and interesting features, foremost among which may be mentioned an illustrated description of Mr. Alfred A. Scott's new frame, the Overseas notes and readers' opinions, points of design in the new Matchless flat twin, and a striking series of double-page illustrations depicting a coastal ramble in the Cape Peninsula.

The Scott frame will, we are sure, evoke unusual interest and comment.

The R.R. Spring Frame Mount.

Last week the Royal Ruby Cycle Co. submitted to the War Office a single-cylinder Royal Ruby-Jap spring-frame mount. This machine was originally described and illustrated, after a road test, in *The Motor Cycle* of February 3rd, 1916. A slightly modified design was reviewed in this journal of November 2nd last.

A Lewis machine gun outfit belonging to the Blackpool Squadron of the National Motor Volunteers—an instructive adjunct. Inset (left), Adjutant S. O. Taylor. Inset (right), Half-squadron Commandant J. Prestwich, to whom, with Commandant A. L. Parkinson, a sword has been presented by the N.C.O.'s and men

THE TERROR OF THE ROAD.

A Plea for the Revival of the Old Spirit.

IN the early days of the motor cycle its riders were recruited almost entirely from the ranks of ordinary cyclists who had developed a spirit of comradeship, which they brought with them into the new field. The result was that one motor cyclist was always ready to help another, and this spirit helped to make the pastime very attractive. In addition, the men of the new order were full of appreciation of the needs of riders of ordinary cycles; and even to-day it is easy to see that very many motor cyclists are recruits from the simpler pastime by the consideration they show their weaker brethren. Unfortunately, there is another element amongst motor cyclists, and their very obvious lack of consideration for other road users is likely to create a great deal of prejudice against a splendid recreation: there is a section which imagines that the possession of a machine driven by power automatically turns the motor cyclist into a being who has a right to ignore all others' rights. Perhaps one cannot do better than illustrate the two diametrically opposed types by an occurrence which is fresh in the mind of the writer:

The Two Types.

It was a peaceful Sunday morning, and standing at well-known cross roads leading out of the Metropolis was a motor cyclist contentedly smoking his cigar while waiting for his passengers to join him. Suddenly his attention was attracted by a fellow motorist approaching the cross roads, and knew that he was looking at an old cyclist when the newcomer slowed down to a walking pace on nearing the crossing, where, in ordinary times, many cyclists would have been found. Riding a lightweight, the motorist got halfway across, when the onlooker caught sight of a sidecar outfit coming at right angles at a furious pace, and reflected that the second man would have to moderate his speed. He was, however, wrong, for, with the lightweight more than halfway across the road, the driver of the combination neither slowed down nor passed at the back of the other machine, as he could have easily done, but simply jumped his engine to something in the neighbourhood of a mile a minute and endeavoured to swerve across in front of the lighter machine. The attempt might have succeeded, but there was not sufficient room, and the handle starter of the powerful combination hooked itself in the front wheel of the lightweight. What followed was truly sensational: the light machine, travelling at not more than four miles per hour, was suddenly switched off at right angles at a terrific speed and its rider shot up into the air, and then crashed down upon his head, unconscious.

Culpable Indifference.

The onlooker sped to his assistance, and was helped by passing cyclists, while the cause of the trouble, whose machine had not even been overturned, coolly watched them without attempting to do anything. Eventually he listened to repeated entreaties and went for a doctor, but it was forty minutes before the unconscious one could get medical attention. He was hurried off to a hospital, and it is understood that after a month of alternating consciousness and unconsciousness he awoke and remarked that he had had a "curious dream." But, and this is significant, the driver of the combination appears never to have even enquired whether the victim was dead or alive.

The incident demonstrates that a new element has entered the motor cycling world, and emphasises the need for strengthening the spirit of helpfulness and comradeship. If the evil spirit triumphs there will be an end of motor cycling as a pastime, and many thousands of people will have lost health-giving recreation; but we cannot but believe that the healthier spirit will be strong enough to exorcise the lower influence, and in that belief we look forward to the days that are coming. CORNUBIUS.

Beach Races in Christchurch, N.Z.

High Speeds on New Brighton Sands. Fastest Speed 67¼ m.p.h.

MOTOR cycle trials and races in the Dominions are apparently suffering in much the same way as they are over here, and very few events have taken place of late. The fact that so many of the leading lights of the various organising clubs have joined up is bound to affect the enthusiasm of those who remain, quite apart from any other motives or consideration. However, now and again race meetings are held, and recently the Pioneer Motor and Sports Club (N.Z.) held three beach races at New Brighton (Christchurch). The beach was very soft, and times might have been even better had the surface been more favourable. There were a large number of spectators to witness the events.

FIVE MILE MAIDEN SOLO HANDICAP.

Place.		Handicap.
1.	J. Mantell (3½ Triumph) ...	1m. 10s.
2.	W. Jones (7 Harley-Davidson)	scratch
3.	G. H S. Smith (3½ Swift) ...	1m. 40s.

Time, 5m. 20⅕s.; fastest time (W. Jones), 4m. 17⅖s. Won by abont 75 yards.

THIRTY MILE OPEN HANDICAP (SOLO).

Place.		Handicap.
1.	W. Jones (7 Harley-Davidson) ...	30s.
2.	F. Haworth (4 B.S.A.)	2m.
3.	H. S. Curtis (7 Indian) ...	1m. 30s.

Time, 26m. 46⅕s., which was also fastest time. Won by about 200 yards.

THIRTY MILE SIDECAR OPEN HANDICAP.

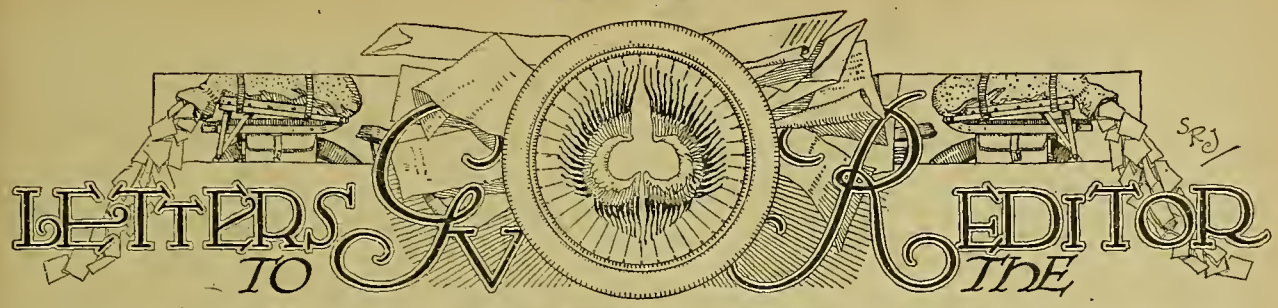
Place.		Handicap.
1.	F. Haworth (4 B.S.A.)	4m.
2.	G. B. Brown (4 Triumph) ...	4m. 30s.
3.	G. Moffatt (4 Triumph) ...	4m.

Time, 34m. 41⅕s.; fastest (W. Jones, 7 Harley-Davidson), 33m. 32⅕s. Won by two lengths.

On another occasion recently the same club held a beach race, also at Brighton Beach. On this day the beach was in better order, and the wind was more favourable. The race resulted:

1.	F. Haworth (4 B.S.A.)	4m.
2.	W. Jones (7 Harley-Davidson)	scratch
3.	G. B. Brown (4 Triumph) ...	5m.

Time, 51m. 46⅕s.; fastest time (W. Jones), 48m. 7⅕s. Won by 300 yards.



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

OUTSIDE FLYWHEELS.

Sir,—May we, through your columns, point out, for the interest of "A.H.S." and others, that we are quite certain of the improvement made by an outside flywheel on a 500 c.c. single, as compared with inside flywheels? We pin our faith to the outside flywheel, and have little doubt that public opinion will support us in this faith.

BURNEY AND BLACKBURNE, LTD.

BEARING PRESSURES AND LENGTH OF STROKE.

Sir,—The impression the "Long *v.* Short Stroke" controversy leaves on one lay mind is, "Six of one and half a dozen of the other." If Mr. Norton were to design and build a medium-stroke engine it would (one imagines) be little if at all inferior to his justly celebrated long stroke!

May one also thank Mr. Bradshaw for his patient, courteous, and lucid letters, and for all his efforts to help us laymen to realise the aims, difficulties, and methods of a progressive designer.

Few of your readers will be inclined to compliment Mr. de Lissa on his controversial methods; but (fortunately for its makers) the excellent M.A.G. engine speaks for itself.

Liverpool. H.K.P.

Sir,—The discussion on stroke proportions has been of great interest, covering as it does ground already well trodden by car designers. I submit that neither party can prove anything of value to either user or producer. To know the conditions imposed by the different proportions of stroke and connecting rod length is to provide for them. This is the art of the engineer.

Referring to car practice, we have cars of both types winners in road racing, and excellent from the users' point of view in respect of bearing wear. And we have others where the necessary allowance for loads has not been made and lubrication has been poor.

The latter is one of the secrets of success; splash will give way to positive in all motors. TILOP.

Liverpool.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—I have just read another letter signed by Mr. Osborne de Lissa, who, I understand, is connected with the foreign (Swiss) made M.A.G. engine, criticising—in some cases sarcastically—the remarks of Mr. Bradshaw, the designer of the British-made flat twin A.B.C. engine. I believe, if the truth were known, it would be found that in the way of mechanical engineering Switzerland has done a very great deal for Hunland during the war. A single firm at Schaffhausen has delivered three hundred motors for Hun submarines; in fact, the latest information from Zurich confirms that a large number of workshops in Switzerland are working on behalf of the German Government. The Matchless previously fitted the foreign (Swiss) made engine indicated by the letters M.A.G., but they are fitting a 6 h.p. British-made flat twin on their post-war model, and quite right, too.

I have written this letter because one can buy a British-made engine which is as good as any foreign one.

Wimbledon Park. A.M.I.E.E.

Sir,—After a perusal of Mr. Granville Bradshaw's letter in your issue of January 25th I am convinced that we are really in agreement on the subject of induction pipe design, particularly as applied to horizontal twins. His mixture-heating experiments prove this. My original remarks on this subject applied to the horizontal twin engine as a type and the first half of his letter merely show that he alone of flat twin engine designers has realised the fact that long unheated induction pipes, as fitted to nine out of ten horizontal twins, are not a factor conducive to good running when the temperature is at a mid-winter level. The *argumentum ad hominem* regarding "hot sides" and intended sarcasm does not clear matters. To paraphrase the offending paragraph: "Can an engine be said to be uniformly cooled when two such dissimilar temperatures can exist 6in. apart in a mass of metal under running conditions?" Is there any objection to a completely exhaust-jacketed induction pipe for a flat twin engine?

A. LINDSAY, M.B., CAPT., R.A.M.C.

Sir,—I have no desire or intention to embroil myself in the discussion now rampant in your columns on the subject of "Flat Twins *v.* Singles." But I feel that a word from a rider of a big V twin is not entirely out of place. I have ridden, in the order given, a 3½ h.p. T.T., a 5 h.p. T.T. (an American), a 2¾ T.T., and I now possess an 8-10 h.p. V twin solo. The former three were in the "dear dead days before" the war, and the last a 1916 model.

In my humble opinion there is nothing to equal it. Certainly not any of the other three. One gets power, acceleration, no fuss, and, finally, speed. When throttled down on top the machine is delightful, and there is none of the jerk so noticeable at low speed on a single, geared high. The sole drawback is weight, but that is negligible when the other advantages are noticed.

What say your readers to the big twin? CE 1942.

London, E.C.

Sir,—May I be allowed to say a few words on the above subject? I have just read Mr. de Lissa's letter in your issue for December 14th, and I consider that he has allowed jealousy to overcome the courtesy due, not only to a fellow correspondent (Mr. Bradshaw), but also to *The Motor Cycle*. Let us have discussions, and well contested ones, but not those which assume a "hot" side (!) through jealousy.

Mr. de Lissa having entered the discussion brings with him the V twin, and this brings me to my questions. Will the V twin survive? Is the 500 c.c. "flat" twin going to oust the 500 c.c. V twin? Are our luxurious 770 c.c. and 998 c.c. sidecar outfits going to be flat twins in, say, 1918? I think so. Will Mr. Collier tell us why he dropped V twins (after remaining faithful to the type so long) in favour of the flat twin?

With regard to the single, I consider it will survive, and so will the flat twins Long and keen will be the struggle for supremacy. At the present time I do not think there is a man living who can say which will triumph. This I do think, the V twin will not be in at the death.

B.E.F. F. MASON, M.T., A.S.C.

Sir,—I am a regular reader of *The Motor Cycle*, and I think it more interesting to-day than ever it was. (Have taken it since first issue.)

Having had some years experience with motor cycles, I should like to express an opinion with regard to the discussion which has gone on for a considerable time in your columns. I used to be somewhat nervous about tackling a machine with a twin engine, thinking a "single" much more simple and economical. Perhaps my opinion would not have changed as it has done had I speculated in a less

reliable "combination" than a Harley-Davidson, which I have had since October last. This is fitted with disc wheels, which are extremely useful, especially when running through snow.

I have given this machine the most severe test which a machine *could* have (in this country), running through deep snow and over atrocious roads. A single would have been *absolutely* no use under the same conditions. The Harley-Davidson has killed all my prejudice against American machines, and I was very much prejudiced before having it. Of course, all American machines are not so good. I hear very poor accounts of some of them. Every part of my machine seems to have had much thought bestowed upon it. Take the clutch, for instance: I have never come across one which works so sweetly, unless it has been on a car.

The many refinements and wonderful reliability of the machine I have mentioned have made me seriously think that there is plenty of room for improvement in most British machines, and certainly more enterprise required by our makers, who *will* stick in one groove and make the excuse that reliability is their chief aim.

I admit that a comparatively low-powered "single" can get off the ground, solo, faster than most high-powered "twins," but I venture to say the average speed, with a substantial sidecar, for a day's run would be very much against the "single."

I will add the usual disclaimer with regard to Harley-Davidson motors. S. BARKER.

Sir,—Mr. Michelmore Hitchcock says a twin-cylinder machine gives double the trouble that a single gives. The plugs on my flat twin have very seldom sooted up. The engine very nearly seized at one time, but both cylinders were the same. Lately broken piston rings caused trouble, but there was one in each cylinder. It seems to me that where a part is duplicated they wear equally, and, I feel certain, not quicker than in a single.

I started up a well-known single of a late type, about 4 h.p., and gave it a short run. Up to about 10 m.p.h. it was jerky. Also it was stiffer than any flat twin I know to start, and it was impossible to make the back wheel turn round when engaged with the engine in low gear.

I have ridden over 2,000 miles on my present back tyre; a great deal with a pillion passenger, and the tread does not yet show signs of wear.

It is not so necessary to keep up the revolutions with a twin, as I have often turned a corner on top gear at 6 m.p.h. without a jerk and also picked up speed again, though I generally change down for that for the sake of the engine.

The use of the magneto advance lever will save changing down and undue wear when running slowly, and this seems a lever which many people leave in one position, viz., fully advanced. At slow speeds the force of the explosion comes before the piston reaches the top of the stroke. No wonder, then, that undue wear takes place.

London, S.W. R.E.C.

WATER INJECTION IN PETROL ENGINE.

Sir,—When I first enlisted I was working in the engine-house of our camp, and among the three engines we had was an old 16-20 h.p. Campbell, with water injection; this was partly for cooling and chiefly for preventing pre-ignition. If it was turned off for a time a most horrible knocking commenced, which stopped as soon as it was turned on again.

As for the chemical action, the action of water steam on red-hot iron (viz., parts of combustion head) would surely be to combine the metal with the oxygen and burn up the hydrogen. For a small and highly sensitive engine like a motor cycle engine water injection must be considered impracticable. (PTE.) W. E. SLEIGHT.

MUDGUARDING.

Sir,—I am always pleased to see letters, like that of Mr. Rycroft's in your issue of January 18th, on the question of mudguarding. This point, to my mind, is far more important than questions of carburetter warming, single *v.* twin controversies, etc. I, too, use a motor cycle daily for business purposes, and the last few weeks' weather has not improved my opinion of the manufacturers, who can supply us with engines like the M.A.G., gear boxes like the Sturmey-Archer, perfect clutches, interchangeable wheels, etc., and yet still continue to give us mud protectors unfit for a perambulator. I strongly object to clothing myself in fisherman's attire every time I must ride even a mile, and yet this is absolutely necessary unless one can afford a new suit every day (which is not absolutely war-time economy). Please keep constantly hammering this point home to manufacturers, as it is quite possible to make motor cycling as clean as motoring, if only the makers will try to produce sensible mudguards.

I would also like to see a guard right under the engine to protect the crank case from mud and dust (I believe the new Matchless is so fitted), and why could we not have metal guards on each side of the engine, to enclose the working parts entirely, leaving the front ends open for a current of air to pass between them on to the cylinders? We have still a lot to copy from the car makers in this respect.

There are thousands of potential riders, who at present look upon the pastime as a "filthy job," and until this bogey is laid will probably remain outside the ranks.

A. S BRADLEY.

AN ORIGINAL RACECOURSE.

Sir,—I am enclosing a photograph illustrating an odd motor cycle race which was staged near here recently by Paul J. C. Derkum and R. C. Obert.

The race was run through the five and a half mile length of the big concrete storm drain at El Molino. Obert won the race, covering the distance in 9m. 18⅘s. Derkum's time was 11m. flat.

The running time was increased considerably by the fact that two miles of the distance was over a cobblestone surface, and the last three miles was through soft mud and water

A race in a storm pipe. (See letter from J. E. Hogg.)

from 3in. to 6in. deep. The drain also has numerous curves, and in taking one of these at high speed Derkum charged the wall, due to a skid (a side-slip, I believe, is what you call it in England). He lost two minutes straightening his handle-bars.

The picture shows the riders neck and neck coming down one of the several water shoots in the course of the big drain.

While this race was a thriller from start to finish, the most remarkable part of it is that Obert won in spite of the fact

that he used a Cleveland lightweight motor cycle, while his opponent used an Indian motor cycle of much greater power. Obert's success is attributed to his ability to handle the little machine on the curves and in the slippery mud and water.

Alhambra, Cal. JOHN EDWIN HOGG.

HEATING THE CARBURETTER.

Sir,—Having read Mr. H. H. Brownrigg's very interesting letter in your issue of January 18th, stating his experiences in connection with heating the air drawn into the main intake of the carburetter of his 4¼ h.p. single cylinder, I should like to give my opinion as to the cause of loss of power and overheating which resulted from the above proceeding.

When air is heated and consequently rarefied and drawn through the main intake, the pressure at the jet orifice is lessened, with the result that more petrol is sucked into the combustion chamber, giving an over rich mixture. Also, the mixture not being of so dense a consistency as cold vapour, cannot be compressed to so great an extent, naturally causing loss of power. Apparently the only solution of the problem seems to be to heat the mixture while on its passage from the jet to the cylinder, to overcome the over rich predicament; but a certain loss of power seems inevitable. GEO. SCOTHERN.

STARTING ON ACETYLENE.

Sir,—There is a small paragraph in *The Motor Cycle* of January 25th which is of vital importance to my Starter jet, that is, a little piece in "Current Chat," page 75, *warning* motorists not to use acetylene gas for starting internal combustion engines. The warning is given by an experienced chemist, who states that all who escape accident when using this system do so by good luck, so evidently I have been enjoying extraordinarily good luck for the past two years. I might say that a Daimler started up O.K., but I should like to give it a good trial. If you do not hear much of me later on, of course you will know myself and friends, present at the time of starting up, have gone hence owing to *accident*. H. G. PASSEY.

Sir,—I see you have a short article in *The Motor Cycle* of January 18th on starting with acteylene, and apparently it receives more or less approval from you.

May I point out the very dangerous character of any such contrivance? I do not in any way question the results said to be obtained, but I am surprised the author of them is still unharmed, and especially so with regard to his machine. The idea is quite old, and has been done with various internal combustion engines, sometimes with, at any rate temporary, success; in others, alas! with accidents, some ending fatally.

The point has only just been raised again in *The Model Engineer* by one who, like your correspondent, tried it. With the marvellous "luck of ignorance" he had not then had any accident; but another reader described a case ending fatally. The least extra accumulation of gas is fairly certain to blow the cylinder off. It cannot be too strongly insisted upon that acetylene, in any case, is a dangerous substance to use as an explosive, and in the case of anyone not an expert in mechanical chemistry it is sheer folly to meddle with it.

Perhaps you are aware that acteylene and oxygen (as opposed to air) is so violently explosive that, even in these days of high explosives (and before the Defence of the Realm Act), the *making* of the mixture is forbidden by law, let alone any attempt to use it.

I myself can claim to be a highly trained and experienced chemist, and somewhat of a mechanic, and I would not on any consideration allow acetylene to be used in any case where I might be able to prevent it. F. C. LEES.

MEASURING GRADIENTS.

Sir,—I see in *The Motor Cycle* for January 18th that the question of measuring gradients has cropped up again. There appears to be a great deal of misconception about this, and, as a railway engineer, it is news to me to learn that on a railway a gradient of 1 in 1 is vertical.

On all engineering works, as I know them, distance is measured truly level; anything else would lead to endless confusion, and it would be impossible to represent a plan on a flat surface. On a railway, where the gradients are usually very flat, the difference in length measured on the rail as against a level length is so trifling that it need not be taken into account in actual practice, but this does not apply in the case of hilly roads.

To produce a profile or section showing the gradients on such a hill as Sutton Bank is quite a troublesome business, as the length of the surface of the road is considerably greater than that taken on the level, and it is the level, or horizontal, length that is required as against the vertical rise in that distance. This denotes the gradient, the surface length not being considered at all. S.L.

Doncaster.

PORT DESIGN ON TWO-STROKE ENGINES.

Sir,—I greatly appreciate "Progressive's" article on two-strokes, and quite agree with his list of merits, but could add another, lightness. As he says, most of the disadvantages have been overcome in most of the good makes. My experience will bear out this statement.

I have owned and driven several well-known two-strokes, also four-strokes, but for an inexpensive lightweight, cheap to run, light on tyres, belts, and petrol, there is nothing to beat a two-stroke.

I have used my machines almost every day, both for business in town and touring, having several times done 130 miles a day on a Baby Levis. My present bicycle is a 1915 Excelsior, Villiers two-speed engine, chain-cum-belt drive, Amac with 26 jet and a large compression tap in induction pipe, which is fully open after starting from cold. I have fitted a 1½in. tail pipe to the silencer, which has improved the running.

The machine will easily climb hills like Sunrising, Fish Hill (Broadway), Weatheroak, etc., on top (5¼ to 1).

With regard to the disadvantages mentioned by "Progressive," I will give my experience with this machine.

Flexibility.—I can ride, with person walking, on bottom gear (8½ to 1), ignition retarded, and accelerate to 40 m.p.h. on top. A four-stroke of the same size is no better, if as good. It rarely four-strokes.

Cooling.—I have had no trouble on this score. I give plenty of oil (drip to induction pipe). I often do sixteen miles, Alcester to home, including climb up Gorcot Hill, in thirty minutes, and the engine is not really hot on arrival home. I had some trouble at first with plugs, but since fitting a Sphinx speed model my troubles have departed. I am going to try the new Sphinx two-stroke plug next time.

Petrol Consumption.—About 100 m.p.g. is my average.

There has been no trouble with crank case compression. The original bearings are still as new after about 8,000 miles, also original piston rings are still running. They never stick in their grooves, as I think I keep them free by injecting a drop of paraffin once a week into the engine while hot. I clean and decarbonise about every 500 miles, which only takes about an hour (a big advantage over four-strokes).

For a rider who is content with a 25-30 m.p.h. pace there is nothing to beat a good two-stroke.

In conclusion, I should like to say that I consider the Excelsior a grand machine, well built, nothing shoddy, compact, and pleasing to the eye. Usual disclaimer.

King's Heath. EXCELSIOR.

A TIP FOR EASY STARTING.

Sir,—In spite of the general easy starting of the 2¾ h.p. Douglas, much difficulty has been experienced during the cold weather in starting up from cold in this part of the country (Newcastle-on-Tyne).

The following tip has been found of great service, and is passed on to others who are riding the W.D. Douglas. Remove the projecting tronser guard on the air intake of the carburetter, and do not refit until warmer days arrive.

Purchase a good-sized cork from an oil and paint merchant, and cut it to the shape of the screwed cover of the air intake, and make a close fit to prevent it slipping off on to the road. On the coldest morning all one need do is to slip this fitting on, tickle the carburetter, a good heave, and off it goes. After mounting, the cork can be removed and put in the pocket.

WILL B. DAVISON (Sgt. D.R.)

[*Owing to the large number of interesting letters received weekly, many have to be held over for want of space. Correspondents are therefore asked to be brief and to the point.*—ED.]

CAM DESIGN.

A Dissertation upon Cams, showing the Reasons for Different Contours. and the Advantages and Disadvantages of the Various Types.

WHILE most people, or, at any rate, most motor cyclists, have an idea of what a cam is, and what function it is supposed to perform, very few probably have troubled to analyse the action of a cam, its whys and wherefores, and so fail to understand why one engine has quiet valves and another the reverse. Also, it is not generally appreciated why one cam wears rapidly, another slowly; why one is suitable for speed work, yet another for touring and slow pulling.

The writer proposes to explain these various points. Fig. 1 shows a cam, tappet, and valve such as would be a common arrangement on any motor engine. In the end of the tappet is a roller, which rests on the face of the cam. In many engines this roller is replaced by a rocker lever as shown in fig. 2, but for our purpose we will use the roller. Having now the mechanism, we must next consider the motions we can impart to it by rotating the cam.

Fig. 1.—Valve arrangement with a roller tappet.

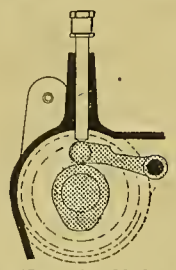


Fig. 2.—Valve gear, showing rocker lever.

There are three distinct motions, any of which, or any combination of which, can be transferred to the roller. Movement of the roller, of course, means that the whole mechanism moves, so I will use the word roller throughout. Now we can consider the three distinct motions mentioned. They are—

1. Uniform Motion.

This is where the roller, having once been started, is lifted a uniform amount for each stage of revolution of the cam. Any object which is travelling at a constant speed, such as one mile in one minute continuously, is travelling with a uniform motion. We must note, however, that in order to travel with a uniform motion, the object must already be in a state of motion. A body which is in a state of rest cannot instantly attain uniform motion. This point is of very great importance, as will be presently shown.

2. Harmonic Motion.

The next type of motion is called harmonic motion. A familiar example of this is approximately the motion of a piston attached by the connecting rod to its crank pin. The piston is brought to a stop by the connecting rod at each end of its stroke, and is reversed, gradually gaining and then losing speed. The projected lines on the diagram (fig. 3) show this more clearly than can be explained.

3. Constant Acceleration and Retardation.

When a body is moved with a constant acceleration, we mean a constant and unvarying force is applied to it. Thus, when the body is still, and offers its greatest resistance to motion, force is applied to it and moves it slowly. The resistance to motion thus decreases, and with the same force applied the speed of the body increases constantly. *Vice versâ*, if we desire to stop the body, a constant force will cause it to stop without shock by retarding it gradually.

Having now fully considered the motions we may employ, I will next revert to their applications, in practice, to cams. My intention is not to confuse the reader with strings of figures, but to endeavour to show how the cams are designed, and what the effect of each will be on the roller. This, I consider, is best done in a graphic form, in which the roller is shown as if it were rotating around the cam. It will be noted, however, that the positions of the centre of the roller during a certain stage of its lift are projected on to a vertical line to make my comparisons clearer. The cams, which are shown at figs. 4, 5, and 6, have been drawn from the following data.

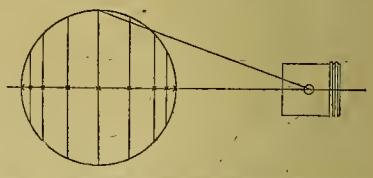

Fig. 3.—Diagram explaining the harmonic motion of a piston.

Valve lift = .4in.
Valve to be lifted in 90° crankshaft rotation.
Valve to remain open for 40° crankshaft rotation.
Valve to be closed in 90° crankshaft rotation.
Diameter of roller = ½in.

Uniform Motion.

The cam, of course, runs at half engine speed, therefore the angle of crankshaft rotation must be divided by two to give the corresponding cam period.

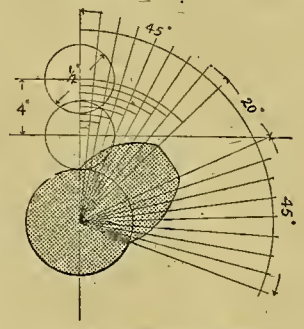

Fig. 4.—Uniform motion.

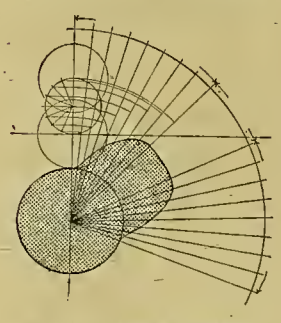

Fig. 5.—Harmonic motion.

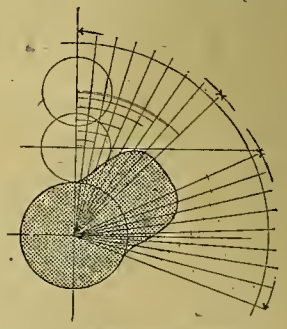

Fig. 6.—Constant acceleration.

Cam Design.—

This is shown on the diagram, the angles being then 45°, 20°, and 45° respectively. From the position where the roller rests on the plain portion of the cam we mark off the centre of the roller. Above this we step off the lift of the cam, viz., .4in. This space can be divided into as many portions as convenient, eight having been chosen in this case. We must remember, however, to divide the angle through which the lift occurs into a similar number of parts. From the cam centre of rotation, the different centres of the roller are projected across as shown.

To obtain uniform motion the roller, having no initial upward motion, must accelerate from nothing to the velocity it has to attain finally in an infinite space of time. This is impossible, and what would occur actually would be that the roller, on coming in contact with the cam face, would attempt to bounce off immediately, then would fly back again, and so on, causing great shock, noise, and wear. As we want the roller to be lifted with the minimum effort, it is clear this cam does not suit our purpose.

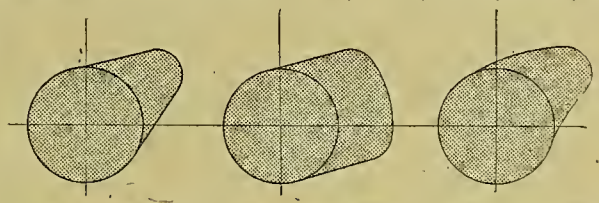

Fig. 7.—A type of tangential cam useful for all-round work

Fig. 8.—An alternative type of tangential cam.

Fig 9.—A cam primarily designed for speed work.

An illustration of this occurring may be helpful. Supposing a motor cyclist moving along at, say, 30 m.p.h. runs into a wall. The impact is terrific, of course, and breaks his machine. This is almost equivalent to what occurs to a roller in the case given. Supposing, now, our motor cyclist uses a constant retarding force, *e.g.*, the brake, he stops himself without damage. This gives a rough illustration of the difference between the action of the uniform motion and constant acceleration cams.

In the case of harmonic motion, shown in fig. 5, as can be seen at a glance, the upward lift of the roller is much more gradual than in fig. 4.

Constant Acceleration.

The most important type of cam, viz., constant acceleration and retardation, is shown in fig. 6. I say this cam is the most important, because it is possible, by its use, to raise and lower the roller with practically a constant force being exerted by the cam. This is a highly important feature, and one upon which too much stress cannot be laid. It means that we can obtain a quiet, durable valve gear which will maintain its original efficiency for long periods. We note on the diagram how the roller is first lifted a small amount, increasing to the middle of the lift, and then decreasing to the top of the lift, thus doing away with the tendency of the roller to fly off the cam face.

Other Cams.

The remaining diagrams, figs. 7, 8, and 9, show three more types of cam. The first two are varieties called tangential cams. This type, especially the first, gives, as can be seen by comparison with fig. 6, a very close approximation to constant acceleration, and, when properly designed, gives very good results. It is largely used owing to the simple outline lending itself well to cheap machining. The last is a type which gives very good results for speed work, but is noisy, and usually unsuitable for touring engines. As can be seen, it gives a rapid opening to the valves, which, combined with an equally quick closing, permits a long dwell open.

Summary and Remarks.

The writer is firmly of opinion that a study by designers of the essentials of cam design would benefit many motor cycle engines. Noisy valve gear is, without a doubt, very much more prevalent on motor cycle engines than on car engines. It is acknowledged, of course, that car engine designers were very much stimulated by the advent of the sleeve valve engine, but there is no reason why motor cycle engine designers should not also improve their products. Noisy valve gear has usually been in the past drowned by a more noisy exhaust, but, as silencers improve, more insistent demand will be made for silent valve gear.

By the foregoing the writer hopes some of the faults and ideals of cam design are made clear, and a little consideration of this article will help to make the reader appreciate the reasons underlying valve gear behaviour.

A.A.S.

Radiating Fins and Aero Engine Practice.

WE have often made reference to the probable influence which aeroplane engine construction is likely to have on the motor bicycle engine of the future, and some little while ago published a series of articles on this interesting subject. Since that time further evidence has been forthcoming that vast strides are being made in moulding and casting, so that now it is possible to cast the most intricate cylinders with twice as many radiating fins per foot as was before commercially possible.

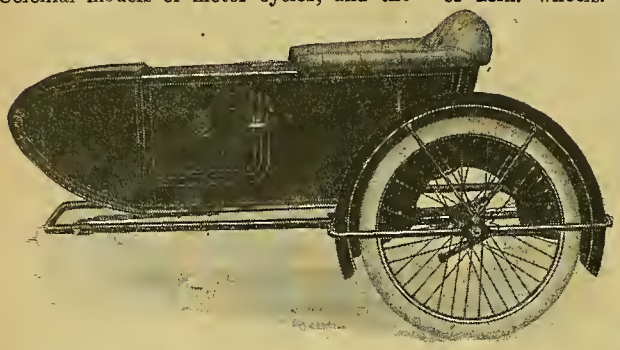
Moulding and casting, where it depends entirely upon the adroitness of the craftsman, enables practically anything to be cast, and the writer has seen the most beautiful designs in foliage, flowers, etc., produced entirely in cast iron, but the methods employed are very different from ordinary foundry work. To produce motor cycle air-cooled cylinders on these lines would be extremely expensive.

From what we have seen we think it is quite probable that motor cycle cylinders will in future not only be cast very much better than ever they have been before, but they will also be cheaper to produce as well as more uniform throughout. Previous to the production of aeroplane cylinders with a large number of radiating ribs set very close together, the ordinary motor cycle cylinder produced a considerable amount of bad language among founders. The aeroplane industry has, however, produced machinery by means of which there does not appear to be any difficulty in moulding and casting air-cooled cylinders with as many ribs as can be got on the barrel. The ribs can also be as deep as before and very much thinner at the edge and the root.

SIDECAR DEVELOPMENTS FOR EXPORT.

A Special Design to Meet Overseas Requirements.

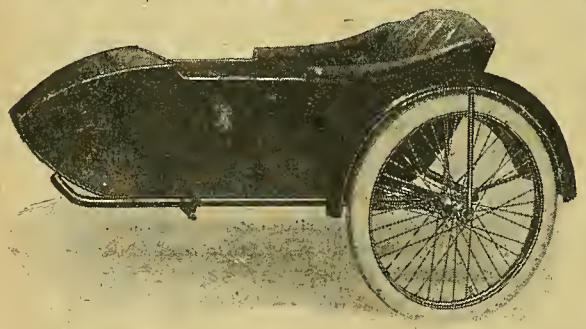
IN furthering our campaign to foster the export trade of this country, we continue to find manufacturers devoting what little time they can spare from war work to the important duty of holding our Overseas markets. Many firms have specialised, from time to time, in Colonial models of motor cycles, and the return of peace will see a marked advance in this direction; but the sidecar, developed in accordance with the many urgent demands from all parts of the world, has been somewhat neglected.



The Empire military model, which is specially designed for Overseas use, having a 12in. ground clearance. Note the six-point fixing of the mudguard.

Messrs. Lowes Empire Motor and Sidecar Co., Ltd., of 159, Great Charles Street, Birmingham, have been concentrating on Overseas models—or rather on special sidecars to meet War Office requirements for active service. This has necessitated the design of a model which will "fill the bill" for the majority of Overseas riders. In order to obtain the ample ground clearance of 12in., the usual type of underslung frame is superseded by a level chassis of extra heavy gauge tubing. Four-point heavy steel forged connections are provided, each embodying a patent quickly detachable coupling. The wheel is exceptionally strong, being built on an unusually wide hub, supported at both ends with heavy gauge spokes. The steel mudguard has a deep inside valance, and is attached at six points; this should effectually prevent the usual destruction by vibration, common with guards having inside supports only. Removal of the wheel is rendered easy by slotted fork ends. Springing is strong yet efficient, the connections to the chassis being a particularly good point.

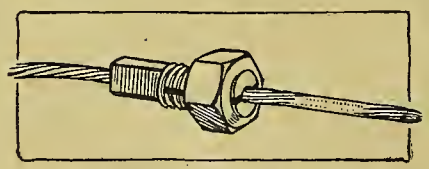
A coachbuilt body on pleasing lines, made up of close annealed metal panels on wood frames, made under a patent process, finished with good upholstery, side doors, and pockets, all go to form a smart and attractive sidecar. A neat screen can be provided if required. A substantial kick-up jack is fitted. This model can be supplied with either 26in. or 28in. wheels. We are informed that numbers of this particular model have seen active service on all fronts, and have given general satisfaction. The makers have, amongst a long list of various designs, one or two other types especially worthy of notice. The Empire lightweight, which turns the scales at about 60 lb., is a very pleasing model, as is also a medium weight, built on similar lines. This has a special point in an extension of the wheel spindle, which carries an outside vertical support for the mudguard, pivoted at the top to lift out of the way when removing the wheel.



A medium weight Empire model, having an outside stiffening rod pivoted to the mudguard.

A NEW BOWDEN WIRE NIPPLE.

THE ingenious nipple for Bowden wires we illustrate can be attached instantly. The end of the wire is first sweated to prevent the edges fraying. The nipple has the ends split and coned, and the fact of screwing a nut over the split cone ensures a tight grip of the nipple. Once the end has been sweated and the nipple placed in position, the wire can be shortened or adjusted without any necessity for further soldering.



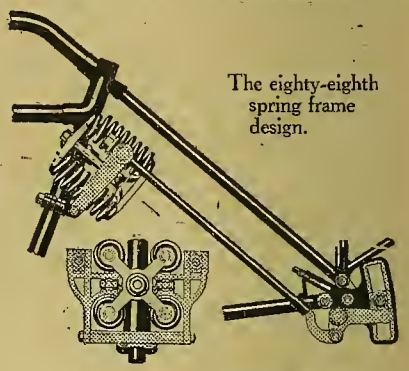
A wire nipple by which the length of cable can be easily adjusted once the end has been soldered.

The device is the invention of one of the mechanics at Messrs. H. Taylor and Co.'s, 21a, Store Street, Tottenham Court Road, London, W.C., who is anxious to sell the rights of manufacture.

REAR SPRINGING.

THE Motor Cycle campaign in favour of spring frames is well known to our readers, and we illustrate on this page a device invented and patented by Mr. M. M. Brophy, of 48, Approach Road, Margate.

The rear axle carries blocks, which slide in slots carried at the rear of the forks, and capable of adjustment for chain or belt stretch. The wheel axle is mounted upon the longer arms of the bell crank levers, while the shorter arms are connected with springs and placed in such a position with relation to the direction in which they act upon the springs that any upward movement of the wheel will tend to move the ends of the short arms appreciably towards the fulcrum of the lever, so that they, acting through a shorter leverage, will have a more powerful influence upon the springs as they are compressed, and their resistance of the latter increases. Thus, it is claimed, bouncing is minimised, and a very delicate adjustment obtained. Reference to the illustration will give a clear idea of the construction of the device.



The eighty-eighth spring frame design.

A rear springing device patented by M. M. Brophy.

"Motor Cycles and How to Manage Them."

Recognised everywhere as the standard handbook on the motor cycle, its care and management. Every motor cyclist, whether beginner or experienced rider, will find the book extremely useful.

Price 1/6 net. By post, 1/10.

"Hints and Tips for Motor Cyclists."

This book gives hundreds of useful "wrinkles" and items of information concerning the running, management, and repair of motor cycles, and contains what may be termed the cream of up-to-date motor cycling knowledge. Altogether nearly 1,000 hints and tips are given.

Price 1/- net. By post, 1/2.

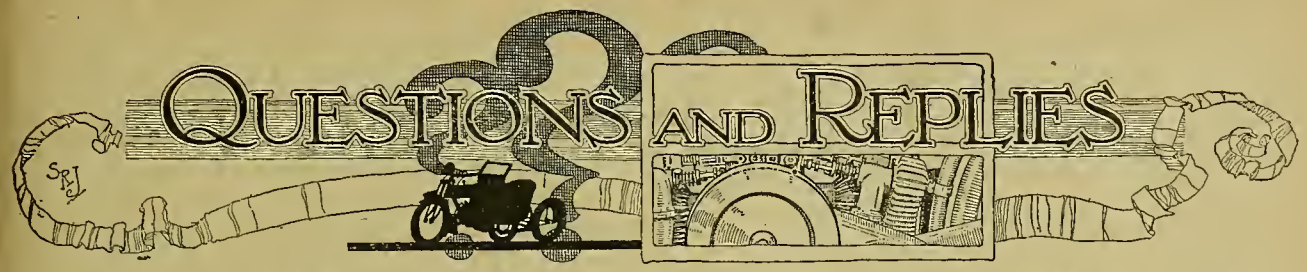
"Tracing Troubles."

Motor Cycle Faults, Their Identification and Their Remedies Fully Explained.

The object of this book is to enable motor cyclists not only quickly to trace the cause of any fault in the machine, but to remedy the trouble in the shortest possible time. The system is applicable to all makes of machines, both four-stroke and two-stroke.

Price 1/- net. By post, 1/2.

Obtainable through leading booksellers, or direct from the publishing offices of "The Motor Cycle," 20, Tudor Street, London, E.C., England.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Again—Which Wheel Lifts?

Owing to an argument that has arisen among the despatch riders of my company, I should esteem it a great favour if you will give me your opinion as to which turning, right or left, one is most likely to turn a motor cycle over when riding with the sidecar attached.—F.C.B.

With the sidecar on the left-hand side of the machine you are likely to overturn the outfit in taking a left turn. In taking a right turn it is almost impossible to upset, the wheels of the outfit merely skidding. With any vehicle the wheel or wheels on the *inside* of the circle tend to lift when cornering at speed.

Broken Valves.

I have a motor cycle fitted with a 2¾ h.p. single-cylinder engine, on which the exhaust valve is continually breaking. I do not think the valve spring is too strong, but I cannot get a valve to last more than 500 miles.—D.L.W.

Your trouble is most likely due to the valves being made of poor material. Have a special valve made of nickel or tungsten steel. The following will often cause valves to break: Too rich a mixture, back pressure in exhaust outlet, running with spark too far retarded, or too strong a valve spring.

Difficult Starting.

I should be much obliged if you could advise me in the following difficulty. I ride a 2¾ h.p. Douglas, 1913 model, fitted with 1916 cylinders, and Binks 1916 three-jet carburetter. I have rung the changes on various pilot jets, and find that when running the correct ones are 000 and 2, as first and second pilots. The trouble is to get the machine to start. After flooding the machine gives a few more or less feeble explosions and then stops. If I open the throttle more than half on to the first pilot it chokes. I used to start up by putting my hand over the air intake, but as I have fitted a hot air pipe, without which the float chamber promptly freezes up, this is now impossible.—J.C.

We think you will get easier starting if you proceed as follows: Make quite sure no air leaks exist in the induction pipe or the carburetter joints, and make certain the contact points are breaking properly and are quite clean, and plugs are in good order, and electrodes are clean and properly adjusted. If all these points are correct start as follows: Before flooding, open the throttle wide so that petrol sprays from all three jets simultaneously. After flooding freely, close the throttle so that the pilot jet only is in action. We think if you try this tip you will be able to start more easily, though, of course, starting difficulties are to be expected in cold weather with present day petrol.

Tuning a Scott.

Will you kindly assist me with your advice *re* 1914 Scott? The machine is in excellent condition, compression in both cylinders perfect, and quite clean internally; magneto timed, when retarded, points broken, piston dead on top. I have fitted new gauzes and crank case packings. The machine is very heavy on petrol—30 to 40 m.p.g.—and does not climb hills on top gear solo, also cannot exceed 35 to 40 m.p.h. (1.) Is it quite necessary to have double gauze to all four transfer ports? (2.) What speed should the machine be capable of, solo and with sidecar? (3.) Is the Scott machine suitable for long journeys with sidecar, passengers' total weight 25 stone?—G.G.

(1.) We do not consider it absolutely necessary to have two double gauzes in each of the transfer ports of the Scott engine. You will find that the gauzes can be separated, and we would advise you to do this and replace them with only one gauze between each of the packing joints. This is particularly advisable when using heavy fuels, which show a tendency to fill up the gauzes with a black glutinous substance. We would imagine that obstruction in these gauzes is probably the cause of your machine being slow on the road, but a Scott never pulls well after having been decarbonised till it has done a certain amount of running. (2.) It is rather difficult to say what speeds the machine should be capable of. It should touch something in the neighbourhood of fifty solo, and forty with a medium weight sidecar, in the hands of a mediocre rider. (3.) Yes, we consider the Scott machine quite suitable for long journeys with sidecar. Being water-cooled, it can carry a fair weight at high average speed without danger of overheating. We note that you have fitted new packings to the crank case. We presume you mean the rubber packings between the cylinders and the crank case. Very great care is needed in making these joints, as the slightest inequality, caused by the twisting of the rubber rings, will entirely upset the running of this engine. Make careful search for air leaks, both about the crank case and the induction pipe.

A Weak Spark.

I have a small Bosch magneto which I can only get to spark by moving the high-tension wire across the field magnets. It will not jump across anything. I have tried altering the size of the gap, but to no purpose. Would you please advise me what to do to make it spark across the points of a plug?—A.W.W.

Make sure all adjustments of the magnets are in order. See that the rocker arm of the contact breaker is not sticking, and that the platinum points are clean and adjusted to break about .4 mm. Also make sure the high-tension carbon brush and holder are in good order and free from oil. See that the switch wire, if fitted, is not shorting. If all these points are in order, it is possible the magneto may require an overhaul or the magnets remagnetising. When rotated fairly fast—say at about 200 r.p.m.—a spark should take place at the plug points quite regularly and jump a gap of about 1 mm. In testing, see that only the body of the plug is touching the metal of the engine or magnets.

Gummy Engine.

(1.) I have a 2¾ h.p. two-stroke, the engine of which gums and locks when running to make a start, the back wheel skids, and on tar macadam it is almost impossible to start. Injecting a quantity of petrol eases the engine, but even then it sticks when starting again. I bought it second-hand; it is about twelve months old. Can you suggest a remedy? (2.) What is the best oil for this type of engine, and the best setting of the drip lubricator, as I have been used to an oil pump?—J.M.

(1.) The exceptional gumminess of your engine may be due to faulty piston rings. Either the rings are too large or are stuck into their grooves. You may be using an oil which is too thick for the cold weather. (2.) Any first-class brand of oil of a light grade, such as Price's, Huile de Luxe, or Vacuum T.T., should be about right. You may possibly experience less difficulty in starting if you give only a very small throttle opening for starting. The correct setting for the drip feed can only be found by experiment, as it varies according to the work being done. Sufficient oil should be given to cause the engine to be almost smoking, but not quite; that is, if the throttle be closed or the engine shut off while descending an incline, upon opening out again a puff of blue smoke from the exhaust should be visible.

Desaxe Cylinders.

I shall be much obliged if you can see your way to answering the following questions: (1) What are the mechanical and theoretical advantages and disadvantages of an "offset" or *désaxè* cylinder? (2.). The *actual position* of the crank pin in relation to the main shaft and gudgeon pin at the moment of the "piston on dead top of the stroke." (3.) Is the balancing of this type of engine any more complicated or difficult?—A.S.

(1.) The chief advantage claimed for an offset or *désaxé* cylinder is that a more direct thrust on the crank pin is obtained; there is also less thrust on the cylinder walls during the explosion stroke. In practice the difference noticeable is small. (2.) When the piston is at the top of its stroke the connecting rod and crank will be in line, and the crank pin will have passed the top vertical position and, in fact, commenced to descend. (3.) The balancing is practically the same as with the cylinder in the usual position, for the amount of offset is never great.

Refusal to Fire on Front Cylinder.

I have been troubled with missing and erratic firing of the front cylinder of my "flat twin." This cylinder will not fire at starting, but after running a few minutes on bottom gear will suddenly pick up until I change into top, then it will again commence to miss. The same thing happens when, after firing regularly, I have to slow down for corners; on opening the throttle it again misses. I may add I am using a Binks three-jet carburetter, and the engine seems to pick up only when opening the throttle fully. I have tested the plugs, valves, tappets, clearance, magneto adjustment, etc., and can find no air leaks. This trouble has puzzled some good mechanics, and if you can let me have your opinion you will greatly oblige.—A.H.L.

We think you must have overlooked some small misadjustment. It sounds very much as though you have an air leak somewhere which affects the front cylinder. A very likely cause is a badly worn inlet valve guide, through which air can be drawn. Weak inlet or exhaust springs might also cause the trouble. If these two points do not prove to be the fault, we can only advise you again to go over all ordinary adjustments; bind all induction pipe joints with adhesive tape to prevent air leaks, make sure that the magneto carbon brushes and holders are in good order, that the insulation of the high-tension cable is quite sound, and make sure the contact points are breaking equally for both cylinders. Uneven lubrication of the cylinders might cause poor running on the starved cylinder, but this is not a likely cause. Whether the fault is in the plugs can be seen by changing the plugs over. See that the air is heated before it enters the carburetter. An improvement may also be effected by lagging the inlet pipe, as condensation often causes erratic running during the cold winter weather. The trouble of poor acceleration is undoubtedly due either to incorrect combination of jets in the carburetter, or to air leaks somewhere in the induction system. For information on the matter of carburetter adjustment we would advise you to write to the makers of the carburetter.

Misfiring.

Would you be good enough to let me know what you think is wrong with my magneto, which is a Ruthardt? The engine misfires badly, from what cause I cannot say, although I have had a motor cycle for five years, and have referred to "Motor Cycles and How to Manage Them." It fires perfectly six times, and then misses about the sixth as regularly as if it were made to fire that way. The points are good and the adjustment correct, the magnet powerful, and the carbon brushes all right. I should send it to be repaired, but I use the machine nearly every day, and from what I hear the makers might keep it for months.—T.B.

From what you say in your letter there seems to be no evidence at all that it is the magneto which is at fault. We should recommend you to overhaul the whole machine, especially the carburetter, which may after all be the source of the trouble. Detach the high-tension wire from the magneto and hold it close to the cylinder, rotating the engine at the same time, and if a spark occurs regularly you may be sure that the magneto is in good order. Make sure that the contact breaker rocker arm is not sticking. Symptoms such as you describe, as you are aware, may be caused by worn throttle slides, air leaks in the carburetter or induction pipe unions, and weak exhaust valve springs. If you definitely trace the trouble to the magneto, all you can do is to send it to the makers or some reliable repairers.

Overhauling.

I have a 3½ h.p. single, and have taken the engine down, and on the spindle each side the flywheels there appears to have been a small peg for the ball bearing cage to fit on, but these have worn or broken off. (1.) Would it be advisable to have them put in again? (2.) Would there be any harm in mixing a small amount of graphite with the engine oil when I put the engine together? (3.) Should there be a small hole in the petrol filler cap? (4.) The oil comes rather freely through the auxiliary exhaust valve down the pipe, and clogs the small holes in the silencer. Can I alter this? (5.) The oil also comes up the tappet guides and through the ball valve on the pulley side. (6.) The engine has a tendency to knock. I have two sparking plugs, one with three points and one with four.—L.B.

(1.) Yes; we should advise you to peg in the ball bearings, as previously done, otherwise they may turn and wear the crank case. (2.) We would not advise you to use graphite. (3.) Yes; there should be a small hole in the petrol filler cap to enable the petrol to flow freely, otherwise the tank will become air-locked. (4.) You might cure this by fitting a stronger spring. (5.) If there is much leakage of oil at the tappet guides, new guides are probably necessary. The ball valve might have a pipe fixed on the end of it, so as to carry away any excess of oil which leaks at this point. Possibly you are giving too much oil. (6.) You do not give us sufficient details to enable us to tell you the cause of the knocking. This may be due to too much carbon deposit, to a loose gudgeon pin or big end bearing, or to the use of a plug the points of which are too light and cause pre-ignition. It is best to use a good single or double point plug of first-class manufacture.

A Gastight Joint.

(1.) My 6 h.p. A.J.S. has detachable cylinder heads, and on sending to the makers for jointing they sent me a copper washer. Is it intended to have a bit of asbestos cord put in the groove of the washer when making the joints? (2.) Is gold size the best thing with which to smear the washer? (3.) What should I use for the joint between the cylinder and the crank case?—R.L.B.

(1 and 2.) The washer ought to have asbestos in its groove. The washer is quite a good one, and if the joints are true does not need any dressing or treating of any kind. (3.) Brown paper soaked in boiled linseed oil; or seccotine or shellac varnish smeared on the paper washer makes an excellent joint.

READER'S REPLIES.

Generator Trouble.

The generator trouble complained of by "H.E.N." on January 11th is caused by overloading the generator. Three lamps are too much for an ordinary generator for really satisfactory work unless the burners are unusually small. The excessive demand for gas causes great heat in the generator; consequently, much steam is generated as well as gas, and the steam condenses in the piping. Even if condensing trouble does not occur the steam causes an inferior light, which is liable to blow or jolt out.—G.S.

Gear Adjustment.

I think "E.G.L.'s" trouble (in *The Motor Cycle* of January 18th), *re* N.S.U. gear, is the same as I have experienced, which was due to deficiency of strength of main spring.—H. C. GRIFFITHS.

RECOMMENDED ROUTES.

BRISTOL TO NEW BRIGHTON.—M.S.

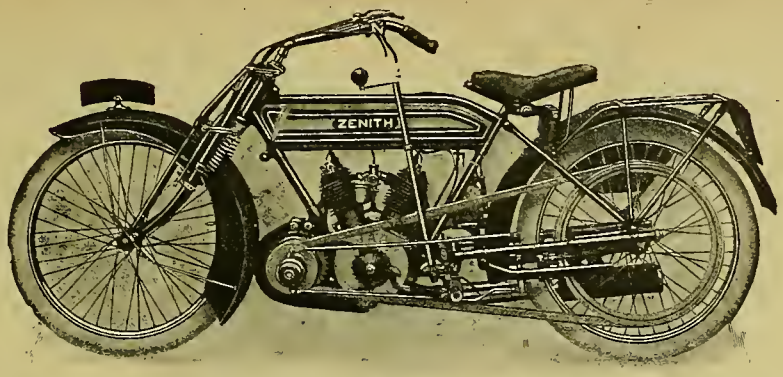
Bristol, Filton, Alveston, Stone, Gloucester, Tewkesbury, Worcester, Kidderminster, Bridgnorth, Shrewsbury, Whitchurch, Chester, Birkenhead, New Brighton. Approximately 93 miles.

WOBURN TO CHATHAM.—C.S.C.

Woburn, Hockliffe, Dunstable, St. Albans, Hatfield, Ware, Hertford, Harlow, Ongar, Brentwood, Tilbury, by ferry to Gravesend, Rochester, Chatham.

BIRMINGHAM TO HASTINGS, VIA DORKING.—A.J.G.

Birmingham, Henley-in-Arden, Stratford-on-Avon, Shipston, Enstone, Oxford, Henley, Wokingham, Bagshot, Guildford, Shere, Dorking, Reigate, Felbridge, East Grinstead, Wych Cross, Uckfield, East Hoathly, Horsebridge, Ninfield, St. Leonards, Hastings.



Equally at home on the track or trackless wastes.

ZENITH

with the Infinitely Variable GRADUA GEAR.

FIRMLY ESTABLISHED on its self-made pedestal of fame, the ZENITH retains its admirers long after other makes have ceased to interest a rider. Recall its record!

THE OIL THAT CIRCULATES EVERYWHERE

Read the reason why **Castrol** was used by the

GREAT WORLD'S RECORD BREAKER

"I have never found an oil to give such excellent results."

Mr. H. C. Pannifex,
Agent for Wakefield's Castrol,
22, Market Street, Melbourne.

Melbourne,
23rd September, 1916.

Dear Sir,—I have used Wakefield Castrol Oil exclusively in my Indian Motor Cycle in my recent World's Records, and I wish to express to you my appreciation of this oil.

During my several years' experience of motor cycle racing and high speed trials and records, I have never found an oil to give such excellent results. I am quite satisfied that a more perfect lubricant than Wakefield Castrol is not obtainable, either for ordinary touring or for racing purposes under extreme conditions.

Wishing you every success with the oil,

I am, yours faithfully,
(Signed) J. R. BOOTH.

WAKEFIELD CASTROL MOTOR OIL

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed ——— & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20 Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisemeat. All replies should be addressed, "No. ooo, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

A.B.C.

1914 3½h.p. A.B.C., 4 speeds, lamps, horn, tools, and spares, very fast, perfect condition; expert examination; must sell; £65, or near offer.—Westend Garage, Hereford. [7813

Abingdon.

ABINGDON King Dick, 1912, 3½h.p., N.S.U. 2-speed, F.E., coachbuilt combination; must sell; owner called up; £20, bargain.—A. Marsh, 29, Capstone Rd., Bournemouth. [7868

1915 5-6h.p. Abingdon, 3-speed, lamps, etc., coach-built sidecar, hood, screen, numerous spares; a good lot, and cheap; £55. All machines advertised by me have been thoroughly overhauled and guaranteed value for money.—Jones, Garage, Broadway, Muswell Hill. [7692

WRITE FOR OUR FULL LIST OF BOTH NEW AND SECOND-HAND MOTOR CYCLES AND LIGHT CARS.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

MOTOR CYCLES FOR SALE.

A.J.S.

A.J.S. 6h.p. 1914 Combination, hood and screen; £60. —Baker and Sons, 35, Friar St., Reading. [X4938

A.J.S. Spares; prompt delivery.—Cyril Williams, A.J.S. Agent, Chapel Ash Depot, Wolverhampton. [X4090

A.J.S., 1914, 2¾h.p., 2 speeds, chain driven, in real good order and condition; £23.—Percy and Co., 337, Euston Rd., London. [X5499

6h.p. A.J.S. Combination, 1916, wind screen, all lamps, tools, and accessories, perfect condition; £90.—Myatt, 736, Oakhill, Stoke-on-Trent. [X5523

A.J.S. 1916 6h.p. Combination, elaborately equipped, only run 600 miles; cost £120, accept cash at once, £90.—77, Tower Ramparts, Ipswich. [X5569

A.J.S., 1916, 2¾h.p., 3-speed, hand clutch, two Lucas lamps, horn, Cowey speedometer, perfect condition; £48, or exchange higher power, Bat, Norton, Zenith.—Lieut. West, Verne Common, Portland. [7901

A.J.S. (late 1915), 4h.p. combination, spare wheel complete with new steel-studded Dunlop, Watford speedometer, lamps, horn, tools, and all accessories, extension and wind screen sidecar, tyres nearly new, machine in perfect running order, only done 3,000 miles, new rings and valves just fitted; any trial or opening up for purchaser; inspection by appointment; a real bargain; cost £116 new, accept £78 cash, no offers.—Gordon, 68, Heybridge Av., Streatham, S.W. [7751

Alldays.

COLMORE Depots, Birmingham and Manchester, for immediate delivery of Allon 2-strokes. [0796

ALLON, Sept., 1915, single speed, original Dunlops; first cheque £20 secures.—1, Felstead Villas, Walton Rd., Clacton. [7753

ALLDAYS Allon, 1916, 2 speeds, clutch model, with 11 gn. C.B. L.W. sidecar; £45.—Croney, 43, Dorchester St., New North Rd., N. [7882

ALLON.—All 1917 models in stock, 36-48 gns.; exchanges and deferred payments arranged.—Maudes', 100 and 136 Gt. Portland St., London, W. Tel.: 552 Mayfair. [7387

Ariel.

COLMORE Depots, Birmingham, Manchester, Liverpool, and Leicester, for all models of Ariels. [0797

RIDER TROWARD'S, 78, High St., Hampstead.—1913 Ariel, variable gear, re-enamelled, fast; 19 gns. [7912

ARIEL, 3½h.p., semi-T.T., with variable pulley gear, fast, and in excellent condition; £22.—Layton's Garage, Bicester, Oxon. [7986

ARIEL, the reliable motor cycle, 3½h.p. single, and 5-6h.p. twin models; delivery from stock.—Colmore Depots, 211, Deansgate, Manchester, and 31, Renshaw St., Liverpool. [0889

I CAN Give Immediate Delivery of 1917 5-6h.p. Ariels, 3½h.p. Ariels, solo or combinations; exchanges or deferred payments. All machines advertised by me have been thoroughly overhauled and guaranteed value for money.—Jones, Garage, Broadway, Muswell Hill. [7699

Auto-Wheels.

SEVERAL Late Model Auto-Wheels, in splendid condition, from £7 to £10 each.—Murray's, 37a, Charles St., Hatton Garden, Holborn. [X5536

AUTO-WHEELS (two), B.S.A. models in stock, £9/15 and 12 gns. each; deferred terms if desired.—Lamb's, 151, High St., Walthamstow, also at 80, High Rd., Wood Green. [7783

MOTOR CYCLES FOR SALE.

Auto-Wheels.

1915 Auto-Wheel, shock absorber, attached 1915 3-speed New Hudson, oil bath, Roman rims, B90 saddle, both in perfect condition; £15/5; separately, wheel £9/15, cycle £6/10; purchasing motor.—Pearson, 15, Grange Rd., Chester. [X5476

Bat.

BATS.—Latest 4-5h.p. sporting model in stock, 2 speeds, etc.; £65/5.—Below.

BAT, 5-6h.p. sporting model, 3-speed hub gear, usual accessories, good condition; £52.—P. J. Evans, John Bright St., Birmingham. [X5589

BAT-J.A.P., 1915, 4-5h.p., 2-speed countershaft, lamps, horn, speedometer, not done 2,000 miles; £40.—Spencer, Biddenham, Bedford. [7745

Blackburne.

RIDER TROWARD'S, 78, High St., Hampstead.—3½h.p. Blackburne, T.T., long exhaust, equipped for paraffin, perfect; 21 gns. [7920

Bradbury.

BRADBURY, 4h.p., and Watsonian sidecar; a bargain, £12; seen Sunday.—104, Grantham Rd., Clapham. [7896

BRADBURY, 3½h.p., N.S.U. 2 speeds, in real good order; £17.—Percy and Co., 337, Euston Rd., London. [X5506

1913-14 Bradbury, 4h.p., 2-speed, free engine, excellent condition; £19.—Gillham, Midhurst, Sussex. [7821

4 h.p. Bradbury and Sidecar, N.S.U. 2 speeds, all accessories, good order; £20.—No. 199, Booth St., Tottington, Lancs. [X5534

BRADBURY, 1912, 4h.p., good order, £17/10; sidecar, low, fit same, 50/-.—Stonbridge, Agnells Farm, Hemel Hempstead. [X5436

RIDER TROWARD'S, 78, High St., Hampstead.—Bradbury, 1913, 4h.p., with 1915 Sturmey-Archer 3-speed and clutch, overhauled; 25 gns. [7913

BRADBURY Combination, 4h.p., 3-speed, F.E., new tyres, first-class condition, spares; any trial; £36.—67, Wigorn Rd., Bearwood, Birmingham. [X5530

Brough.

BROUGH, July, 1916, 3½h.p., 3-speed, clutch, kick starter, mileage under 1,000, excellent condition, exceptionally fast; £58; owner in Egypt.—Apply after 6 p.m., 51, Berlin Rd., Catford, S.E. [7819

BROUGH, horizontal twin, 1915, 2-speed and free, not used for a year, lamps, horn, spares, etc., tyres and belt as new, property of officer at sea; £35 cash.—Fleetwood, Royal Naval Hospital, Haslar, Gosport. [7751

Brown.

3½h.p. Brown Engine, Bowden countershaft gear, Bosch mag., cane S.E. sidecar, 26×2¼ tyres, wheels, lamps, tools; cheap best offers; called up.—70, Bowler St., Levenshulme, Manchester. [X5527

B.S.A.

B.S.A., 1917 models H and K, with sidecars, in stock.—Moss, Wem. [X5561

COLMORE Depot, 261, Deansgate, Manchester, for immediate delivery of B.S.A. [0798

B.S.A., 1916¾, mileage 750, £56; sidecar, £2/10.—127, Ivor Rd., Sparkhill, Birmingham. [X5538

B.S.A., 1913, 3½h.p., 2-speed, free engine, lamps, etc.; £30.—Ainsworth, Aynho Park, Banbury. [X5465

272-274, GT. WESTERN RD., GLASGOW

MOTOR CYCLES FOR SALE.

Matchless

7-9h.p. Matchless, Mills-Fulford sidecar, in fine order, electric lights, numbers, etc.; £73.—Cross, Effingham Sq., Rotherham. [X5521

MATCHLESS 8B Combination, 1915, new tyres, everything complete, in first-class order.—Turner, 12, Church St., Macclesfield. [X4921

MATCHLESS, 1913, 6h.p. J.A.P. engine, clutch model, in good order, very fast; £35.—R. Lear, 52, High St., Harriseahead, near Tunstall, Staffs. [7815

MATCHLESS 1915 7-9h.p. M.A.G. Combination, 3-speed, enclosed chain drive, all perfect, Lucas accessories, Cowey; £85.—211, Deansgate, Manchester. [7469

7-9h.p. Matchless Combination (M.A.G. engine), 3-speed countershaft gear, clutch and kick starter, complete with Lucas head lamp and generator, Lucas horn, rear lamp, speedometer, tools and spares, very little used, and in fine order and condition; price £85; easy purchase terms if desired.—Harrods, Ltd., Motor Car Dept., Brompton Rd., S.W. [7858

MATCHLESS Combination, M.A.G. engine, 3 speeds gear box, clutch, and kick starter, fully equipped with Lucas head lamp and generator, 2 horns, pump, tools, and spares, very little used, and in excellent order and condition throughout; £85; easy purchase terms if desired; exchanges entertained.—Harrods, Ltd., Motor Cycle Dept., Brompton Rd., London, S.W. [7743

Minerva.

MINERVA, 8h.p. twin, Bosch, N.S.U. 2-speed, free engine, sidecar, new tyres and belt, sound condition, fast; £15 cash.—Box L3,035, c/o *The Motor Cycle*. [7769

MINERVA, 2¾h.p., m.o.v., special racing engine, dropped frame, low built, T.T. bars, 26in. wheels, in guaranteed perfect order; £8/10; after 8 o'clock or week-ends.—64, Mill Lane, Brixton Hill. [X5480

New Hudson

3½h.p. New Hudson Combination, 1914; cost £84, sacrifice £42.—Parker, St. Giles', Oxford. [X5397

NEW Hudson, 2¼h.p., 2-speed, 2-stroke; £38.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter, and Tavistock Rd., Plymouth. [0840

1914 New Hudson, 3½h.p., 3 speeds, and clutch, kick starter, and accessories, in good condition; £30.—82, Caledonian Rd., London. [7871

1915 2¼h.p. 2-stroke New Hudson, in perfect condition; £22, or near offer.—Wellboy Garage, Woodford Rd., Forest Gate. Tel.: 309 Stratford. [7736

1913 4h.p. New Hudson, 3 speeds, new tyres and tubes, very nice machine; £28.—Wellboy Garage, Woodford Rd., Forest Gate. Tel.: 309 Stratford. [7737

NEW Hudson 1912-13 3½h.p. Combination, 3 speeds, clutch and starter, good condition, £28; 1912 combination, £22.—P. J. Evans, John Bright St., Birmingham. [X5591

1914 4h.p. Greg. New Hudson Combination, 3-speed, handle starting, in good condition; £40, or near offer.—Wellboy Garage, Woodford Rd., Forest Gate. Tel.: 309 Stratford. [7738

NEW Hudson, 1913, and wicker sidecar, 3-speed, 4 h.p., free engine, new tyres and belt, lamps, and horn, guaranteed perfect mechanical order; £25, or separate; after 8 o'clock, or week-ends.—64, Mill Lane, Brixton Hill. [X5479

NEW Hudson 1914 4h.p. Coachbuilt Combination, high grade underslung sidecar, countershaft 3-speed, clutch, kick starter, spring footboards, Lucas accessories, little and carefully used, new condition throughout, mileage under 2,000; £45.—Box L3,043, c/o *The Motor Cycle*. [7968

1915 4h.p. New Hudson and Sidecar, 3-speed countershaft gear box, all in splendid order and condition, all lamps, etc.; £52; deferred payments arranged. All machines advertised by me have been thoroughly overhauled and guaranteed value for money.—Jones, Garage, Broadway, Muswell Hill. [7705

New Imperial.

J. A. STACEY, 12, Ecclesall Rd., Sheffield, for 1917 Imperial-Japs. Immediate delivery. [7862

NEW Imperial, 2½h.p., 2-speed, and kick start models, just arrived.—Gittins, Ltd., Oswestry. [X5401

COLMORE Depots, Manchester and Leicester, for immediate delivery of New Imperial motor cycles. [0805

RIDER TROWARD'S, 78, High St., Hampstead.—1915-16 New Imperial, 2-speed, perfect order; 25 gns. [7915

1917 New Imperial-Jap, 2¾h.p., 2-speed, as new, all accessories; £38.—Green, 89, Wymering Mansions, Maida Vale, London. [7853

BIRMINGHAM Agent, P. J. Evans, John Bright St. —1917 New Imperial models in stock for immediate delivery; 2¾h.p. 2-speed models, 38 gns.; also clutch models for light sidecar work. [X5593

NEW Imperial 1917 Models for immediate delivery; model 1, 39 gns., No. 2 46 gns.; several second-hand 1916 machines from £30.—Colmore Depots, 211, Deansgate, Manchester, and 31, Renshaw St., Liverpool. [0886

Norton.

NORTON Big Four and Sidecar, brand new; first cheque £89/10 secures.—Percy and Co., 337, Euston Rd., London. [X5500

New Motor Cycles by Permit.

AS will have been gathered by recent observations in these pages, the outlook for manufacturers not exclusively engaged upon war work has been rather obscure, as the permits in their possession allowed them to carry on the production of motor cycles only until the 15th inst. It was suggested, too, that this date might be final, but we are glad to say that several firms have now received permits to carry on for another few weeks when the position will again be reviewed, but the proviso which has been in existence in the car world for some time past has now been extended to motor cycle manufacturers. This is, that no new machines may be supplied without the permission of the Ministry of Munitions, which means that any buyer who can show that the purpose for which he requires the machine is of national importance, such as doctors, farmers, members of the military and naval services, and munition works inspectors who have constant journeys to perform, will be able easily to obtain a permit. Even so, it is added, most naturally, that the assembling of new motor cycles must not interfere with the manufacture of munitions. One probable effect of this Order will be to send up the already inflated prices of second-hand machines.

Mud—What is its Proper Place?

WE offer no apology for reverting for the thousand and first time to the hackneyed subject of mudguarding, for, although at the time of writing the roads are thickly covered with beaten snow, yet we know that wet skies and muddy roads are sure to be with us again before long. A letter from a rider of a lightweight complains that his front guard is cut away to make room for the forks, and that in wet weather a constant stream of mud issues from this opening, spattering both rider and engine with filth. The rear mudguard, he says, is apparently devised to keep the belt nicely lubricated with mud and water. This possibly is an extreme case; still we know, both from our own experience and that of others, that standard mudguarding leaves much to be desired. As a rule, the front guard is the greater offender, but it certainly has the more difficult task to perform. The mud blown back from a rear guard is left behind, that blown back from a front guard reaches both machine and rider unless it is trapped by splash guards. The side valances of a front guard are not much use because mud simply runs down them and drips from the edges or blows back from the forks and mudguard stays. Also the valances make the guard more difficult to clean and more likely to get choked. This can very easily happen with slushy snow, as we found out to our cost recently.

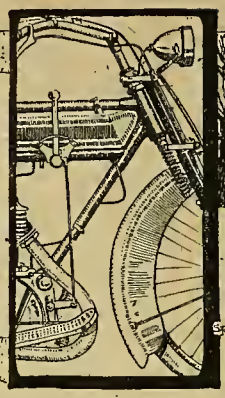
The extra wide guards extending beyond the forks seem to be the most efficient and satisfactory standard guards at present on the market, but these are fitted to very few makes of machine. They could, we think, be improved by being made with a continuous slope downwards from front to rear, and the edges turned upwards and inwards to act as paths down which the liquid mud could run. Thick mud would stick in these grooves, but being accessible they could easily be cleaned.

There are, as of course we are aware, several excellent splash guards on the market retailed by the accessory houses, but when a man buys a first-class mount he ought not to have to spend money in rendering it fit to ride in winter. Again, it is not difficult for a rider to fit efficient (but ugly) splash guards for himself, but after all is said and done this is a question that should be tackled by the manufacturer. It is really extraordinary that so few machines are fitted with screens beneath the engine. These are not at all unsightly, are easily attached and very useful—moreover, they protect both engine and silencer from a great quantity of objectionable road dirt.

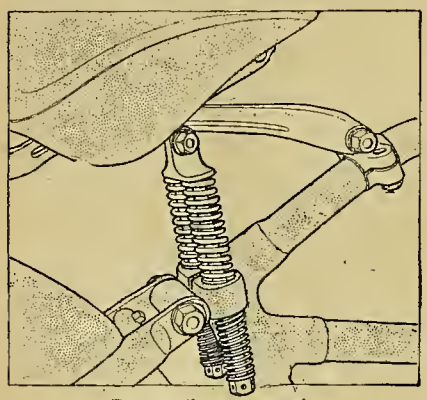
An index to the advertisements in this issue will be found on the page facing the back cover.

SPRING SEAT-PILLARS.

The Desirability of Comfort. A Good Substitute for an Entirely Sprung Frame.



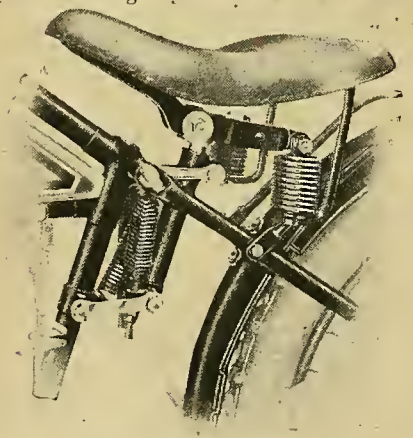
THE ideal spring frame is slow in materialising, but in its absence it is encouraging to note that many makers are endeavouring to render their machines more comfortable by the introduction of spring saddle pillars. Several



Rex cantilever suspension.

firms have already adopted them as standard, though others still regard them as an "extra." Although this type of springing is not so good as the ideal spring frame would be if it could be evolved, it is certainly a simple way of adding to the comfort of the rider.

In nearly all designs of the fully sprung frame that have so far been manufactured very many difficulties arise. Among other points, the rigidity of the rear wheel has had to suffer, if not at first, as soon as slight wear takes place. Rigidity of the rear wheel is an important point to be considered. Lack of it causes most unpleasant sensations when taking sharp turns at speed or when negotiating difficult stretches of rutty or greasy road. This disadvantage may easily counteract the advantage of increased comfort gained by the springing. The insulation given by the spring seat-pillar, although insulating only the rider from road shocks, at any rate permits the rigidity of the rear wheel to be maintained, and also allows for a simple construction of the frame, which is, of course, an important point if the price of the complete machine is to be kept down. The spring seat-pillar was perhaps one of the earliest attempts to reduce road shocks, and it will be remembered that a most excellent example was on the market incorporated as a standard fitment on the Rex models as early as 1907. Probably the chief disadvantage with the spring pillar is that the riding position is necessarily somewhat higher than it would be with the ordinary saddle attachment, but with the low built frames of to-day this can really be overlooked. Among the many machines now fitted as standard with these extra springing devices—or on which a device can be included if specified—may be mentioned the following leading makes: Clyno, Ariel, A.J.S., Rex, and Leader.

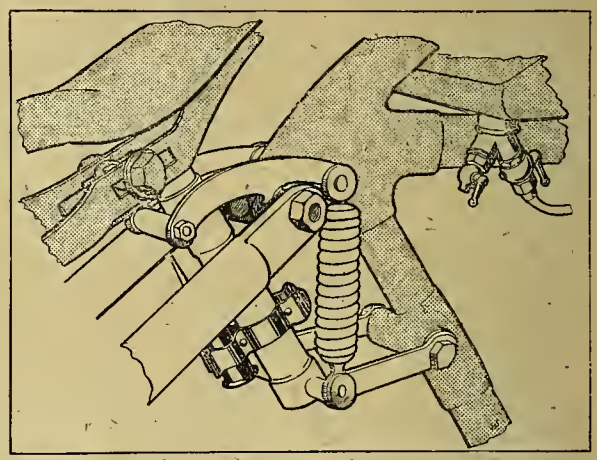


The Ariel saddle suspension is based on front fork principles, the auxiliary seat-pillar being adjustable to various weights.

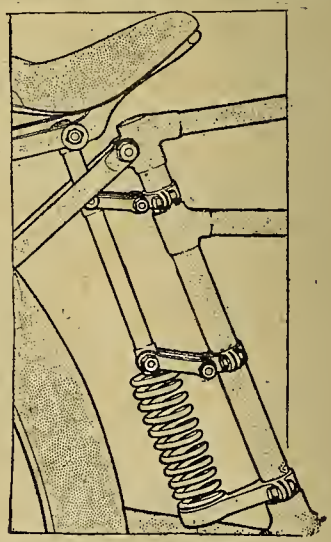
An Early Model.

The spring seat-pillar fitted to the Rex de Luxe since 1907 is quite a simple affair, and is on the cantilever principle. The tube on which the saddle is carried is hinged at the foremost end, where it is attached to the cycle frame by means of a clip. Amidships are two guide rods, which pass through two guide lugs cast on the saddle lug of the machine. Above the guides are the two main springs, while below are situated two springs to take the rebound.

The Ariel device is on front fork principles, and consists of an auxiliary seat-pillar carried at the rear of the frame saddle tube, to which it is connected by four rocking links. The springing is obtained by two suspension springs, while a third spring is provided to absorb the recoil shocks. The auxiliary seat-pillar is adjustable to a



On the latest Clyno a spring saddle-pillar is used, also based on the front fork principle.



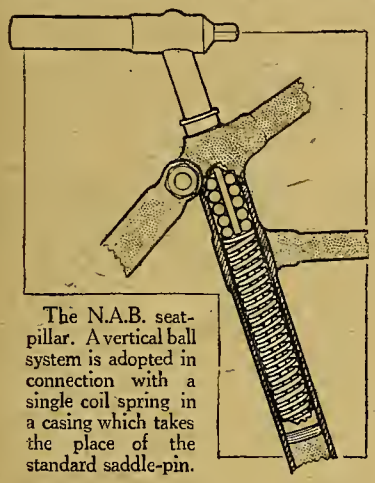
The A.J.S. device consists of an auxiliary saddle tube, beneath which is one large compression spring.

Spring Seat-pillars.—

certain extent to suit the weight of rider, while if so desired it can be entirely removed, and an ordinary seat-pillar fitted in the usual way.

On the latest War Office model Clynos the spring saddle-pillar is also on the spring front fork principle. The saddle pin proper telescopes into a tube which is connected to the cycle frame by means of four links. The attachment to the frame is by bolts passing through specially designed lugs brazed to the frame; two tension springs sustain the load.

The A.J.S. device, though not a standard fitment, can be had as an extra on any model. It consists of an auxiliary saddle tube situated behind the usual saddle tube of the frame. The auxiliary tube is attached to the frame by means of two pairs of links, the clips that secure the device to the frame being detachable. The springing is obtained by means of one large compression spring situated beneath the auxiliary saddle support to which one end of the spring is secured, the other end being supported on and attached to a stout bracket which is clipped to the down tube.



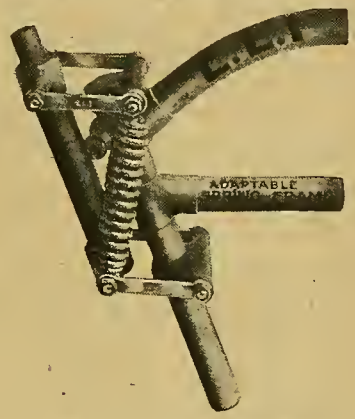
The N.A.B. seat-pillar. A vertical ball system is adopted in connection with a single coil spring in a casing which takes the place of the standard saddle-pin.

Auxiliary Attachments.

Apart from the machines fitted with standard spring seat-pillars, there are now attachments available for fitting to existing motor cycles. Among these, probably the best known is the N.A.B., which has been on the market for many years. The pillar fits in place of the usual standard saddle pin, and consists of a solid pin telescoping in a casing, which fits in the usual saddle-pillar tube. The pin is supported on a strong coiled spring, and rows of ball bearings are inserted in grooves between it and the outside casing, these being to preveut the movable pillar from jamming, and to give a free and easy movement. The saddle is mounted on the top of this movable pin, and an adjustable top is provided for the purpose. The N.A.B. can also be obtained in a form which clamps to the down tube of the bicycle frame, and so gives a very low riding position. It will suit machines not fitted with the usual hollow saddle tube.

The E.L.I. adaptable spring frame manufactured by Eli Clarke, the well-known Douglas rider of Bristol, is another serviceable spring saddle attachment which will fit practically any machine.

It is really an adaptation of Druid fork design to the saddle-pillar. The saddle-pillar proper is attached to the down tube by means of links, as in the spring fork, these being secured to the tube by means of substantial clips. Two strong coil tension springs extend from the frame pivot of the upper links to the floating pillar pivot of the lower links, the weight of the rider being, therefore, supported by these springs. The motion given to the saddle would be exactly the same as that of the front spring forks.



The E.L.I. is another adaptation of front fork springing, and is easily attached to any machine.

RACING IN CHILE.

Success of British Machines in Santiago Speed Trials.

THE most important motor cycling event of the year held at Santiago de Chile took place recently over an oval course measuring nearly 1,700 metres (just over one mile). The course has a fair surface, but, as it has no banking, excessive pace is impossible, but speeds of 56, 59, and 62 m.p.h. over the lap were attained.

Junior Race.

The competitors were divided into the following classes: Class I. for machines under 350 c.c.; Class II. machines under 450 c.c.; Class III. under 500 c.c.; and Class IV. unlimited. Class I. contained the following entries: three Junior Triumphs, one Wanderer, one Alcyon, one F.N., and one Brown, while Class II. contained four N.S.U.'s, three Peugeots, and one Humber.

Classes I. and II. were run over the course concurrently, one of the Triumphs, ridden by H. Wilson, failing to get away; but later this rider put up some extraordinarily fast laps, and worked himself into the fourth position. In the sixteenth lap Corson (Peugeot) retired with engine troubles, and on the twenty-seventh lap Wilson ran into first place. Subsequently, however, his tyre burst, and though he tried to finish, the tyre came off the rim, throwing the rider at the very last turn. Results:

FIFTY KILOMETRES.

CLASS I.

1. A. Checa (Alcyon, 271 c.c.)
2. A. Friedemann (Wanderer, 251 c.c.)

Speed 37¼ m.p.h.

CLASS II.

1. L. Poggi (Humber, 350 c.c.)
2. J. Birrer (N.S.U., 396 c.c.)

The Senior Race.

The Senior race was very keenly contested between the Triumph, Harley-Davidson, and Indian machines. The Triumph riders put up some marvellous riding, attaining speeds of 58 and 59 m.p.h., the American machines proving heavy to handle for the constant cornering at speed. Maillard, the crack rider of the Valparaiso Moto Club, experienced trouble with the belt of his Trinmph twisting, and after putting up a splendid race was forced to retire. F. Bolt, an Indian rider, retired on the nineteenth lap, and on the twenty-fifth lap one of the H.D. riders came to grief, luckily sustaining no serious injuries. Results:

HUNDRED KILOMETRES.

CLASS III.

1. F. Moreno (T.T. Triumph, 498 c.c.), time 1h. 24m.
2. F. Larios (Kynoch-Jap, 499 c.c.)
3. E. Betteley (Motosacoche, 495 c.c.)

Won by three laps. Speed 44.4 m.p.h.

CLASS IV.

1. A. Macchiavello (Triumph, 550 c.c.), time 1h. 19m. 16⅘s.
2. C. Grunnert (Harley-Davidson, 998 c.c.)
3. R. Maira (Indian, 998 c.c.)

Speed 47 m.p.h.

THE ANNUAL GENERAL MEETING OF THE MOTOR CYCLING CLUB.

THE annual general meeting of the M.C.C. was held at the Café Monico, Piccadilly Circus, London, W., on Wednesday, January 31st. Mr. E. M. P. Boileau was invited to take the chair.

The only business of the meeting was to receive the annual report and statement of accounts.

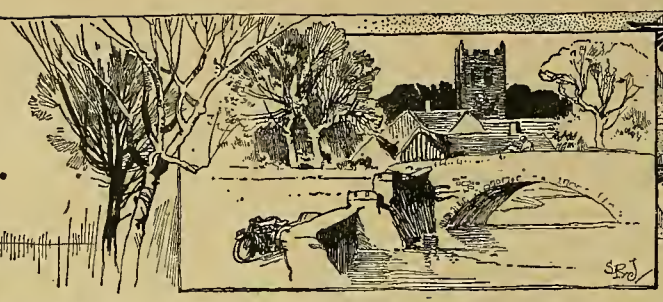
During the meeting it was announced that Mr. Arthur Millbourn is acting as hon. sec. *pro tem.*, and Mr. W. H. Wells is doing the work of treasurer.

It was proposed by the Chairman and seconded by Mr. H. Taylor that the officers of the club and committee should be re-elected for the present year. The auditor, Mr. W. Richards, was also re-elected.

Mr. Wells proposed and Mr. Armstrong seconded the proposal that no applications for subscriptions should be made to members during the war. The proposal was carried *nem. con.*

Mr. R. H. Head, chairman of the club, mentioned that the hon. sec. of the club, Mr. Southcomb May, M.M.G.S., had been wounded in East Africa, and was in hospital at Cape Town. Another member of the committee, Mr. E. B. Dickson, had also been wounded.

Protection from the Mud.



SOME WAYS OF KEEPING DRY AND CLEAN WHILE RIDING.

FOR many months, both editorially and in the Correspondence columns, *The Motor Cycle* has attempted to bring home to manufacturers the desirability of adopting light, easily removable leg shields as a standard fitment, and it is to be observed that our efforts in this direction are slowly but surely yielding fruit. The motor cyclist who has once realised the comfort of efficient shields takes badly to a machine that is not so fitted; indeed, he regards the ordinary motor cycle, which necessitates the donning of heavy overalls even for the shortest of winter spins, as a monstrous thing to be avoided, not only on account of discomfort, but from an economical point of view as regards boots and clothing. Leg shields of some sort he must have, and if these are not supplied by the makers he may have some difficulty in obtaining a pair to fit his particular mount. Rather than go without he makes some sort of attachments of his own, which, though generally serviceable, do not as a rule improve the appearance of the machine.

A quickly adjusted spat form of spring overall.

Mudguarding is not, of course, a matter either for home attention or for the accessory maker, since in reality it should be attended to by the manufacturer; but, since the accessory maker has hitherto held undivided possession of the market, we append descriptions of some of the latest shields to come before our notice.

A COVENTRY MOTOR CYCLIST'S IDEAS.

THE following ideas have been carried out by a well-known Coventry motor cyclist owning a Rudge sidecar, who thus describes his devices:

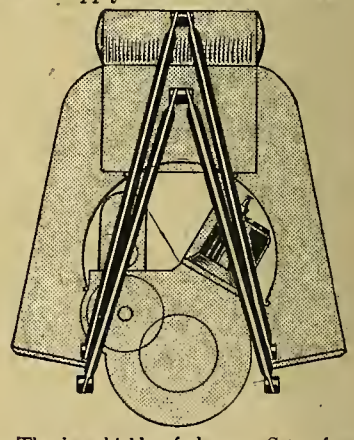
"I have a small pair of spring gaiters, also another larger pair, which come above the knee and protect the thighs. To these I have made the following alterations, which some may consider improvements. I first found the strap *under* the boot required very neat adjustment if the spat were to lie snugly on the boot. If loose enough to slip over the boot it was too loose to hold the spat down. When muddy it soiled the hands in undoing the buckle, and also it was a long way down to stoop (it is some time since I was able to touch my toes). Accordingly I cut out this strap altogether, and increased the size of the spat by sewing on another piece of black leather, known to shoemakers as 'Kip.' It looks rather like a car washer's clog now, but keeps the boots clean, as they are entirely covered. I found the spring alone insufficient to retain the legging securely, and after leaving one behind after a vigorous running start I sewed the two halves of a long strap just below the knee. These cross behind the knee and buckle in front where I can see them, and fasten in comfort. I find the longer leggings quite comfortable and warm enough for half an hour's run, even in cold weather. But the leather saddle strikes horribly cold to the seat. I often think a spring-on padded saddle cover would sell."

The same writer continues: "The roller blind screens to protect the legs from front wheel mud are hard to obtain of late, but I have made some very good imitations, which fasten on to a flat steel bar carried from a clip bolted to the tube above the tank, and carried at the bottom by a similar steel bar bolted on to the silencer or footrest. These are not so bulky as the tin trousers one sees on a well-known make, and do not rattle.

"When riding in the sidecar in really muddy weather, when the roads are covered in 'soup,' I find that the mud runs down to the end of the mudguard extension and then blows back into the passenger's face, in a most objectionable way. After trying several dodges, I have attached an extra section of mudguard on either side of the existing one It looks smart, and bids fair to be successful."

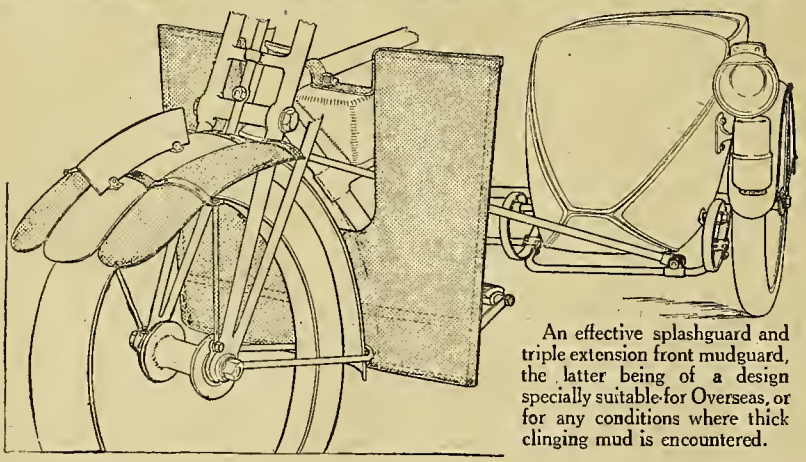
ARTISTIC SCOTT ATTACHMENTS.

THE Scott motor cycle is the only machine at present marketed with adequate leg shields as a standard fitment, although the Sunbeam and P and M. supply them to order. The Scott



The leg shields of the new Scott frame (described on page 96 last week) effectively protect the feet and legs of the rider.

shields afford an excellent example of elegant design combined with usefulness. The curves and harmony of colour of the shields give the finishing touches to the machine so far as appearances are concerned, while not only do the shields protect the rider, and indeed the whole of the mechanism from

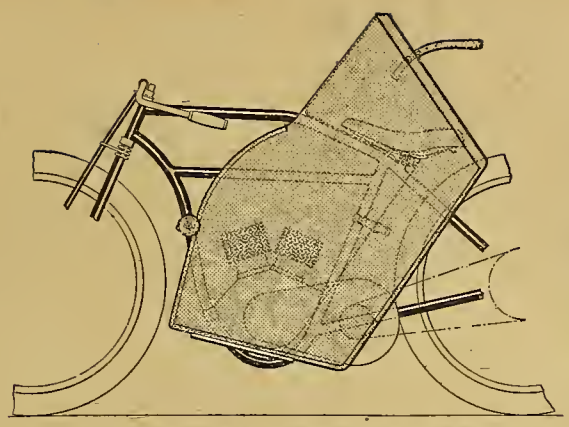


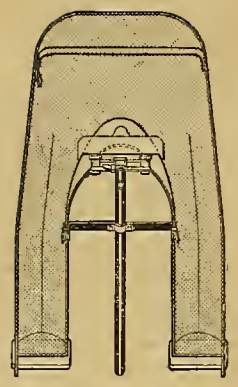
An effective splashguard and triple extension front mudguard, the latter being of a design specially suitable for Overseas, or for any conditions where thick clinging mud is encountered.

Protection from the Mud.—

road contributions, but they effectively concentrate the draught into the channels where it is required.

It is not surprising to note, then—indeed, we should have been disappointed otherwise—that in the design of his new detachable tube frame, which we described and illustrated last week, Mr. Scott has made very ample provision for the comfort of the rider. The roomy leg shields are arranged entirely to enclose the rider's legs, as will be seen from our illustration, while concentrating the current of air on the engine. Given a front wheel mudguard of sensible design nothing further is required.





A combined apron and leg shield in either leather or American cloth, adaptable to any type of machine.

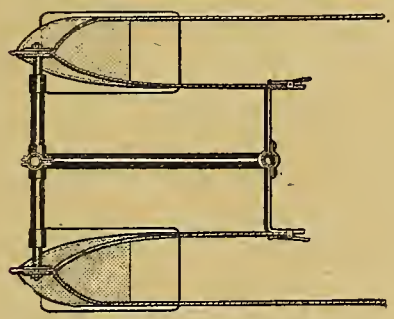
A POPULAR AND EFFECTIVE SHIELD.

A DEVICE on more permanent lines, which we have seen very extensively used in Midland towns, consists of two metal shields, which are curved to encircle the rider's feet and legs. These shields are rigidly attached to the footboards, and also by a bracket to the top bar of the machine, and afford excellent shelter for the rider's legs. They are made by Messrs. Joy and Co., of Foleshill Road, Coventry, and though the firm are at present working almost exclusively on munitions of war, they hope at a later date to be able to supply several kinds of metal leg shields.

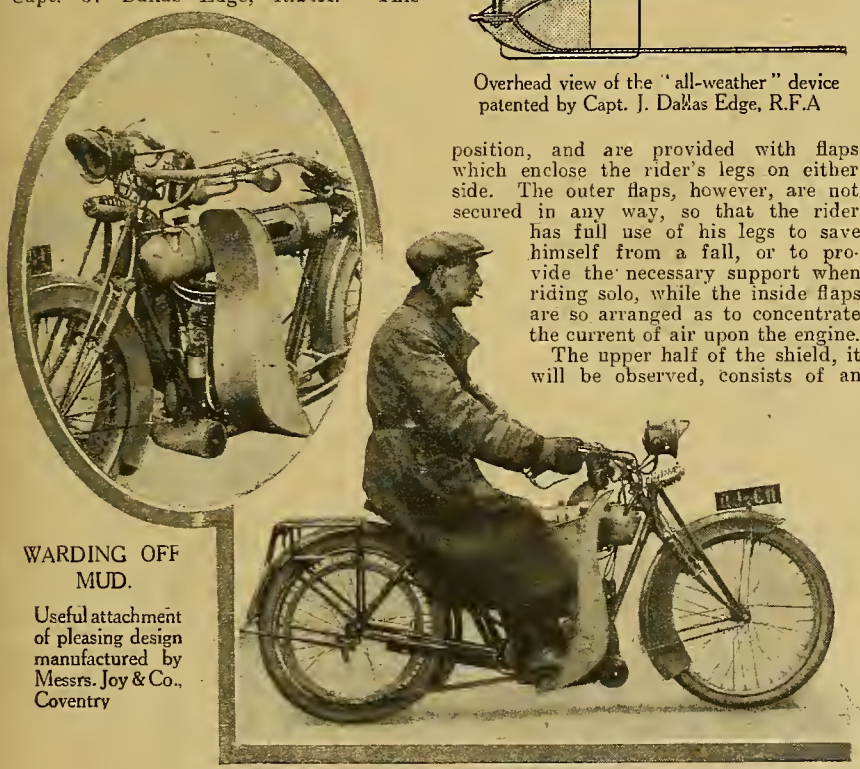
A COMBINED APRON AND SHIELD.

A SHIELD of a somewhat similar nature, only constructed of waterproof material, such as leather or American cloth instead of sheet metal, is the patented invention of Capt. J. Dallas Edge, R.F.A. This attachment is made not only to shield the legs of the rider, but also to provide protection where protection is most necessary, and it may best be described as resembling a pair of capacious overall trousers, having the legs open down the back and made to straddle the tank. These leg members are stiffened by the use of front stays so as to retain their position, and are provided with flaps which enclose the rider's legs on either side. The outer flaps, however, are not secured in any way, so that the rider has full use of his legs to save himself from a fall, or to provide the necessary support when riding solo, while the inside flaps are so arranged as to concentrate the current of air upon the engine.

The upper half of the shield, it will be observed, consists of an apron, which is strapped round the rider's body. This device will undoubtedly provide all the shelter and protection that could be desired.



Overhead view of the "all-weather" device patented by Capt. J. Dallas Edge, R.F.A



WARDING OFF MUD.

Useful attachment of pleasing design manufactured by Messrs. Joy & Co., Coventry

AVERAGE PRICES.

WE give below the average prices of second-hand models offered for sale in *The Motor Cycle*. Difficulty in obtaining a sufficient number of one particular model often arises, owing to the fact that many advertisers omit some of the most essential details.

PICTURE a discharged D.R., a successful but distinctly human manufacturer, a quick-thinking, slow-speaking, and long-experienced journalist, and a fourth individual, whom we had best refer to as the "Novice." They were seated around a fire discussing things in general and nothing in particular, when the Novice remarked that he was about to buy a motor cycle. "A double-purpose mount," he explained with an airy wave. "Something I can ride solo or take my wife about in; but I'm hanged if I know whether to get a 3½ h.p. single or a twin of about the same size."

"For a start, don't expect a 3½ h.p. to do all you want with a sidecar," drawled the Journalist. "I would buy a 4 h.p. single if I were you."

"Why a single?" asked the Novice. "I like the even purr of a twin much better, and I am told it runs much more smoothly than a single."

"If you are going to be decided by even purr," growled the Manufacturer, "why not buy a musical box and be done with it? You remind me of a reverend friend of mine who bought a horse because he liked its tail!"

"And in the end," remarked the D.R., "the selected horse kicked its tail off, just as the selected 'single' is sure to kick its belt off."

The Novice was not to be put off by cheap jokes, and meant thrashing the subject out. Turning to the Journalist, he invited more comment. "A single pulls better for its size than a twin," the Journalist told him, "though it is not so comfortable solo. A beginner can more easily locate a fault in a single, and can keep it in better tune."

"All of which we have heard before," sighed the D.R., stretching his legs to the fire. "A one-legged cyclist can bump along at a good speed, but it's beastly for the man on his step. As a matter of fact, a twin requires very little more attention than a single."

"Very little," agreed the Journalist, "but still a *little* more."

"Even so, the only advantage of the single," announced the D.R., "lies in its low compression and heavy flywheels, which enable it to slog along with optimistic determination; but it is not comfortable to ride, and, what's more to the point, *there is absolutely no suitable transmission for a big single*, and the transmission counts for everything."

What is a Suitable Transmission?

The Manufacturer was obviously bristling. "What do you mean by 'suitable transmission'?" he demanded.

"One which will absorb the terrific thump, yet give a desirably positive drive under all weather conditions."

"What about sidecar machines such as the P. and M. and Sunbeam singles?" queried the Novice.

"Great snakes!" snorted the Manufacturer. "I ought to know a bit about the subject, and I am certain that half the difference is imaginary. You hear the exhaust of a single, and with every pop you imagine a snatch. If the exhaust were silent you wouldn't talk so much about the snatch, because it is almost imperceptible without something to keep time with it. The Journalist is right in recommending a single to a novice of advanced years. Haven't the War Office bought P. and M.'s and Triumphs by the thousand because they know all sorts of men will ride them?"

"And because they knew they'd keep their tune," added the Journalist, with journalistic disregard for clear English.

"Or tear out their spokes in the attempt," mumbled the D.R., looking as though he'd trodden on the teeth of a garden rake and the shaft had jumped up and hit him on the nose.

Some Unparalleled Achievements.

The Manufacturer pointed the gnawed stem of his pipe at the discharged soldier. "You make a test on a long punishing hill," he advised. "There is no twin made which will keep on slogging like a single of the same c.c."

"What is c.c.?" mildly interposed the Novice.

"Cubic centimetres or current consumed," explained the Journalist.

"Oh!" said the Novice, stoutly, "that makes a lot of difference in upkeep."

The D.R. said it was enormous. "You don't have to keep putting pennies into the meter," he explained.

Such frivolity was beneath the Manufacturer. "Take Jack Haslam's performance on a 3½ h.p. Premier sidecar in the 1914 Six Days, or Haswell in the 1913 trials with a 3½ h.p. Triumph outfit. They both beat dozens of solo riders on more powerful machines than theirs."

"I seem to recall that George Brough put up a correspondingly marvellous performance when he went through the Scottish on a 5 h.p. twin *with fixed gear* and got a *Gold!*" observed the D.R. crushingly.

But the Manufacturer was lighting his pipe.

"I forgot to mention," modestly interposed the Novice, who realised that he had lighted a straw and set fire to a haystack, "that I haven't much money to throw about."

The Question of Price.

"Money!" spluttered the Manufacturer, eagerly seizing the point. "Then, again, buy a single. You get better value for your outlay, because it costs much less to make than a twin——"

The Critics.—

"*That,*" interrupted the Journalist, "is why manufacturers prefer it. Slip the belt on again."

"It has fewer parts and less machinery," the Manufacturer pointed out, "and is cheaper to run——"

"About ninepence a week," put in the D.R.

"As for snatchiness in the drive, you are overdoing it. There is undoubtedly more of it than in a twin, but for a novice this really is not worth consideration. A suitable shock absorber, cushion drive—even a spring frame. Just wait till the war is over!"

"Yes," said the D.R.; "you manufacturers are great on the 'just wait' proposition. You say that a single will keep on pulling on gradients, but is there anything more objectionable than that thump—thump—thump on hills? It costs you more in tyres and transmission than the difference in oil and petrol."

"You seem to forget," the Journalist interposed, "that the primary object of this conversation is to enlighten a novice, a juggins, who anyway will thump his engine till it backfires."

"Not I!" yelled the Novice. "I shall change gear at the bottom of the hill and let her rip."

"That is rather risky," pointed out the D.R., sagely. "It is apt to turn the grease in the gear box into margarine."

Keeping Up the Revs.

But to the Manufacturer life was a tense drama. "It's just as easy to change down on a single as on a twin," he pointed out. "D.R. will probably retort, 'And that transforms snatch into vibration.' True, but vibration is not an inherent defect of the single. D.R. has either tried bad samples, or has driven them jolly badly. It comes to this—will you have the offensive smell and extra oil consumption on hills of the twin, or a sticker in the shape of a comparatively cool-running single?"

The Journalist moved his chair. It was his room—his fire, his cigarettes on the table, yet he was crowded out of the cheery circle. "As for overheating," he remarked, drily, "personally I am not experiencing it. The Manufacturer would make a better leg shield than a radiator—if he really tried."

"Oh, but he's a bright spark!" observed the D.R.

"All the same, I agree with him in advising a single as a double purpose mount for a beginner," the Journalist went on. "But I certainly do not back up his statement that vibration is not an inherent fault of the single. A single cannot be properly balanced, so we have to depend upon the transmission for making up what the engine lacks. Hence D.R.'s statement that there is no *suitable* transmission for a big single."

The D.R. graciously handed the Journalist one of his own cigarettes, and at this juncture the Novice announced that he was rather more smitten with the idea of a single. Retention of power he considered a big advantage. "And tinkering," he added, "is not much in my line."

"No," agreed the D.R., his eyes upon the comfortable amidship dimensions of the Novice, "it is apt to burn one's waistcoat."

"But," added the Novice, "what about transmission troubles in wet weather?"

The D.R. looked at the Manufacturer and groaned. At length the Journalist rose to the occasion. "I should say you will have them if you decide upon a single with any form of belt drive," he announced. "But they will not be painfully frequent."

"And snatch?" queried the Novice. "Can I obtain a single which will be devoid of sn-atch?"

"No!" bellowed the D.R.

"Yes!" growled the Manufacturer.

"Snatch is not noticeable, except at low speeds," announced the Journalist.

There was a long silence, the only sound to be heard being that of the Journalist's dog scratching himself under the table.

"Decided what to buy?" queried the Journalist.

The Novice brushed his capacious waistcoat. He was still uncertain, but one demand he knew would be answered definitely and promptly. "Kindly pass the water," was his final request.

WITH MOTOR CYCLISTS ON THE FRENCH FRONT.

Telegraph, telephone, and motor cycles are by no means the only methods of communication in warfare. The exclusive photographs reproduced were taken in the Champagne sector. (Inset) False batteries originally made to deceive the German airmen, but by now well known to them. The Triumph belongs to a despatch rider attached to a famous 75 mm. French gun battery. (*Passed for publication by the French War Minister.*)

Induction Pipe Design.

MOTOR cyclists in general must tread cautiously where the experts are quarrelling, but it seems to me that the controversialists are inclined to confuse two very different factors in inlet pipe design, namely, the temperature of the pipe and its length. I have heard our best designers assert *ad nauseam* in public and private that long induction pipes are the best. Mr. Bradshaw is only saying what I heard Mr. W. Wells say in the old Vindec days (? 1905 or thereabouts). He remarked at a club discussion that he had made bench tests of the 5 h.p. Peugeot engine, in which he was then interested, with inlet pipes ranging from the minimum practicable length up to about 5ft., and that the longer the pipe, the better the carburation in respect of power, acceleration, and economy. But, as modern practice, *e.g.*, on the Triumph, shows, a warm inlet pipe and a warm carburetter are also essential; and, if we adopt a long inlet pipe without any provision for heating it, we may score a trifling advantage in summer, only to lose it and a bit more in winter. A long inlet pipe, in conjunction with heating, secures all the possible advantages.

Capt. Lindsay on the Subject.

AS Capt. Lindsay is dragging me into this controversy, let me describe my experiments in "lagging" the inlet pipes of flat twins. I have two such machines at the present moment. Both have long inlet pipes. One has a two-lever carburetter with a heating system which I can only describe as rather makeshift and inadequate; the other has a single-lever automatic carburetter with a very efficient heating system. I have tried both machines, with the induction system heavily lagged and unlagged; and I have tested both machines over many thousands of miles, alike in summer and in winter. The imperfectly heated long pipe behaves admirably in summer; in winter it is very sluggish at first starting out, whether lagged or unlagged; when lagged, it produces its best running much sooner in cold weather, and apparently runs slightly better for the lagging, even when it is warmed up to its natural limit of temperature. In other words, it benefits from inlet pipe protection, simply because its carburetter is not sufficiently heated. The other machine, having a more generous system of exhaust heating for the carburetter, shows no benefits at all from being lagged; lagged or unlagged, it misfires and is apt to choke in all weathers when first started up, simply because its carburetter is adjusted for a hot air supply and no hot air supply is present until the engine has warmed up its exhaust pipe, and because no adjustment is available to correct the initial absence of hot air. In other words, the motor car type of carburetter behaves on this engine exactly as it behaves on a motor car, and exactly as it behaves if bolted up to the stub inlet pipe of a 4 h.p. Triumph. There is not a word to be urged against the long inlet pipes of flat twins provided they are adequately heated, and this can be done at a manufacturing cost of about 6d. per machine. The 2in. stub inlet pipes of many popular single-cylinders are efficient, not because they shorten the travel of the incoming gases, but because they conduct heat to themselves and to the carburetter; the single-cylinder engine would not show a less efficiency if its inlet pipe were a foot long, provided the pipe and carburetter were kept as hot as the present types.

Motor Cycling and Toothache.

THE medical article in our issue of January 25th reminded me vividly of a time when I was on the point of abandoning the motor cycle, because of the violent toothaches generated by each cold or windy run. Finally I solved the difficulty by making it an absolute rule to visit the dentist once a quarter, whether there were signs of toothache or not. I can recommend this dodge for people whose teeth need retuning at frequent intervals; it saves money, it preserves the teeth as incipient decay is nipped in the bud, it ends toothache, and it prevents a ride or a tour from degenerating into misery on occasions. To wait till a tooth aches before visiting a dentist is really as silly as waiting till a piston seizes before lubricating it. But we were never a logical people. The Chinese pay their doctors when they are well, and the doctor's money ceases while his patient is ill. Perhaps when the Chinese really take up motoring they will hire their motors from makers and agents, and the instalments will be suspended when the motor won't go!

Steel Radiating Fins on Iron Cylinders.

MOTOR cyclists who have not previously seen an A.B.C. always comment on the beautiful evenness and extreme thinness of the radiating fins on my engine. There is naturally a marked contrast between the cast fins of an ordinary iron cylinder and the machined fins of a cylinder which is turned out of the solid steel ingot. But the latest news from America indicates that it is possible for a manufacturer to retain the conventional cast iron cylinder, and yet to have machined steel fins of paper thickness. The air-cooled Franklin car has a six-cylinder engine with overhead valve gear and vertical fins of machined steel. The fins are placed in the mould before the molten iron is poured in to cast the cylinder barrel. It might even be possible to go one better, and to incorporate machined aluminium fins on cast iron cylinders. This should give us very high efficiency in cooling, whilst adding little to the cost of the engine.

MILITARY NOTES.

NEWS OF MOTOR CYCLISTS FROM FAR AND NEAR.

Flight Sergt. R. S. Scoon in flying regalia.

IN THE FLYING SERVICE.

R. S. SCOON will be recalled by many readers as a prominent member of the Newcastle and District Motor Club, and a frequent competitor in North-country reliability trials. He mostly rode a Nut-Jap. Scoon is now a Flight-Sergeant, and was recently home on seven days' leave, during which period he took the opportunity of tying himself up in matrimonial bondage. Scoon is stationed at a flying school in England, and is connected with the instructional staff.

FROM AGENCY TO REPAIR SHOP.

JACK MILLS, who was so well-known as a competition rider prior to the war, has lately been promoted to the rank of Lieutenant R.N.V.R., and is in charge of a repair depôt attached to an R.N.A.S. Transport Section.

A NAVAL WEDDING.

FLIGHT-LT. JOHN FORGAN POTTS, who previous to the present crisis was a frequenter of Brooklands track, on which he used to race on an Indian, and who is a motor cyclist of long standing, was married at Brompton Oratory to Mlle. Lucotte Bultinck, a Belgian lady. We wish the happy pair all success and prosperity.

THE SILENT TANKS.

A GUNNER in the Heavy Section, M.G.C.—the section operating the Tanks—remarks that they are in winter quarters, as will be gathered by the absence of mention of the Tanks in the official *communiqués* of late. They are experiencing quite a change away from the noise of guns, but are nevertheless kept busily occupied "tuning up" the engine, chassis, and transmission. "My word, the oil and grease we use! We are far better off than the infantryman, who has to spend his time knee deep in mud and water," he writes. "As a matter of fact, though many people imagine the Tanks to be dangerous, I would not care to transfer to any other corps. It is the infantry who are winning, and will ultimately win this war. We men of the Tanks often admire the bravery of the men who fearlessly dash over the parapet with bayonet fixed. Why, again, compared to bombing expeditions, a cruise on a Tank in the enemy's lines with plenty of protection is as nothing."

EX-WORKS MANAGER IN HOSPITAL.

SGT. PETER MOSS, who may be remembered by Midland motor cyclists owing to his connection with the motor cycle department of the Premier Co. is in an English military hospital suffering from rheumatic fever. Moss joined the Motor Machine Guns over two years ago, and was quickly promoted to sergeant. He has been employed at one of the repair bases in France for some time past.

R.F.C. MOTOR CYCLIST RECRUITS.

WE have received a grateful letter of thanks from Maj. R. Mitchell, R.F.C., The Polytechnic, 309, Regent Street, London, W., for the work done by *The Motor Cycle* in obtaining recruits for the Royal Flying Corps. Motor cyclist recruits over 19 years of age, and in medical categories A or B1, are still needed. There are also vacancies for Motor Transport drivers in medical categories B1 or B2.

A DARING AIRMAN.

MAJ. F. W. GOODDEN, R.F.C., who was killed while flying last Sunday week, executed some sensational flights on the occasion of the last R.A.F. motor cycle race meeting held in October, 1915. While the competitors were waiting at the end of the straight previous to a race he flew down the track, turned round, and sailed down the straight again just ahead of them. Not noticing the wires running from the club buildings to the timekeepers' boxes, he crashed into these and smashed them, narrowly escaping death in so doing. Immediately after this he banked sharply to the left and climbed steeply over the club buildings. Maj. Goodden was an exceedingly skilful flier, and will be sadly missed at Farnborough

"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS TANKS. A LETTER OF APPRECIATION WAS SUBSEQUENTLY RECEIVED FROM THE ARMY COUNCIL.

A MESSAGE FROM MESOPOTAMIA.

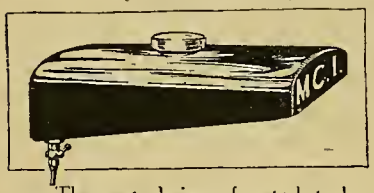
AMONG our correspondence last week was a letter from that well-known L.M.C. exponent, Sgt. Leonard A. Bees, who, it will be recalled, enlisted in the Motor Machine Gun Service in 1915. He is now in Mesopotamia driving an armoured car, and attached to his battery is a large number of Douglas motor cycles, which are receiving a thorough testing in the heat and the sand. The motor cycling conditions in Mesopotamia have been enlarged upon in these columns by Cpl. A. J. Sproston, the heat and the sand being particularly trying both to riders and machines. Sgt. Bees's letter, dated November 14th, was intended as a New Year wish to his friends, and he winds up his interesting communication with the hope that motor cyclists may be reunited at a show next November.

An unofficial photograph showing the "straffing" of a Triumph motor cycle by boys of the R.F.C. The pose is becoming rather too common in military circles and shows a manner in which motor cycles were never intended to be tested.

THE SIMPLEX POWER UNIT.

Another Promising Development in the Direction of the Motor-assisted Pedal Cycle.

AS long ago as November 18th, 1915, we reviewed in these columns a clever attempt to solve the problem of the mechanically-assisted pedal cycle. Its originality was evident, and, despite certain doubtful departures from accepted methods, it promised well. In the interim the design has been considerably advanced beyond the patent stages—one or two experimental models are actually in being—and but for the fact that the British Army requires all the shells it can get, this interesting little motor would be on the market in large numbers. Agencies have already been arranged for export to Overseas markets, and the numerous enquiries regarding it which followed our description of the original design show the interest evinced. We illustrate the attachment as fitted to a New Hudson cycle for testing purposes, and whilst the later models will embody several alterations in detail, the general design remains the same. The first noticeable feature is that it is a *complete* unit, the only separate parts being the controls and the driving chain ring. No alteration to the cycle is needed, and the average cyclist with a little mechanical "gumption" could fit it to his machine in a very short time; an expert mechanic might do the job in five minutes.

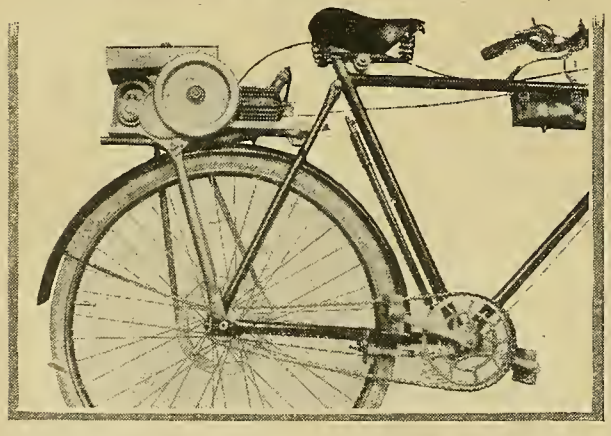


The neat design of petrol tank intended to be fitted on later models. Note the filler cap, which forms the lubricating oil measure.

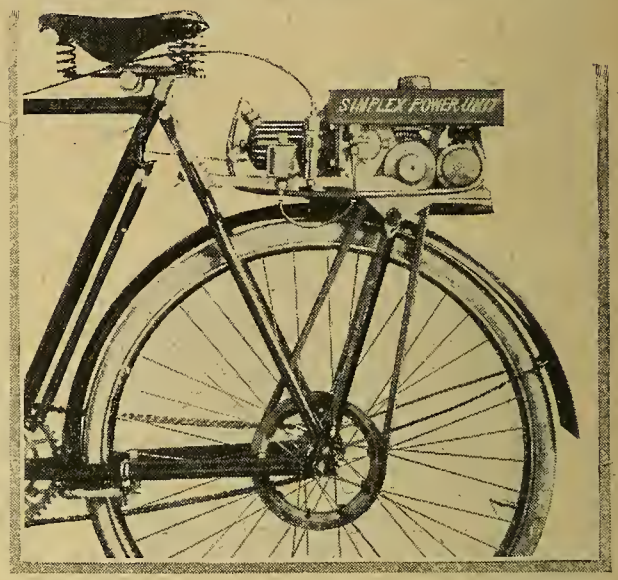
The bedplate for the unit is an aluminium frame of girder pattern, supported at three points, one coupling to the back stays below the saddle, and two oval tubes to the back axle, where they are carried on special nuts, somewhat like the usual cycle mounting step.

The Two-stroke Engine.

A simple three-port two-stroke engine, placed horizontally (capacity about 2in. × 2in., giving approximately 1 to 1⅛ h.p.), drives by gearing to a countershaft carrying a small clutch, continuing by belt to the back wheel. It is geared down to about 10 to 1.



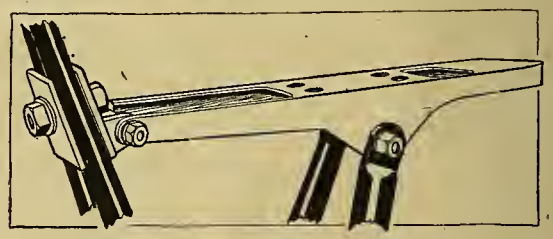
Flywheel side of the 1 h.p. Simplex conversion set.



Simplex power unit, which, as will be seen, is mounted on an aluminium bracket in place of the usual carrier.

(The experimental models are belt-driven, but this transmission will give place to a chain and sprockets.)

The double cone clutch controlled by a handle-bar lever is very efficient in practice. The engine can be started by a pull on the flywheel, the clutch let in gently, and the power is sufficient to get away from a standing start on the level. A small type M.L. magneto, gear driven in the same train of wheels as the main drive, supplies the spark. The carburetter is still to be decided upon, the inventor being engaged in perfecting a special design to suit the small engine. The exhaust is carried to the rear to a small silencer, and the usual sound is nothing but a gentle "purr."



The aluminium carrier bracket, supported at three points, on which the whole unit is assembled.

Great Accessibility.

The tank illustrated is only a temporary affair. The finished article, holding three pints, will be lower, with a rounded top and flat end to take the registration number. Lubrication is by the petroil system for simplicity, the filler-cap cover serving as a measure of the correct amount to a full tank.

Accessibility is a special feature. By removing four bolts the upper half of the crank case can be removed, and the whole crankshaft, flywheel, connecting rod, and piston can be lifted out at once. The release

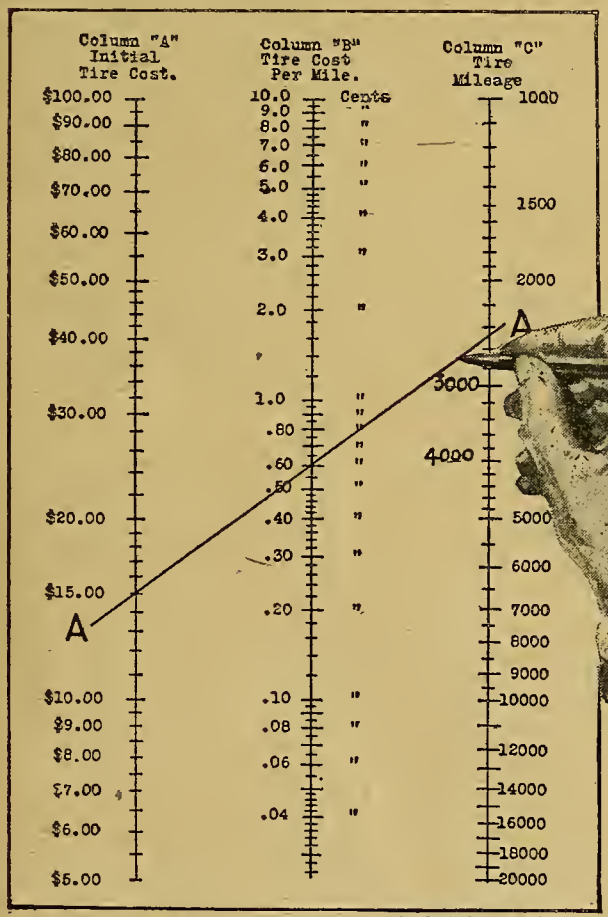
The Simplex Power Unit.—

valve is coupled up to the throttle control cable so that it opens immediately the throttle closes.

The total weight of the unit will be under 20 lb., and the price is not likely to be over £10. At that figure it should be within the reach of all and sundry. The overall dimensions are 16in. × 8in. × 8in. As to its capabilities, we shall speak in a later article, when we have had time to test it properly, but we are informed, and we have no cause to doubt, that it will carry an average rider on the level at a good 16 m.p.h., only requiring pedal assistance on stiffish hills; it has climbed easy slopes of about 1 in 15 at 9 to 10 m.p.h. without assistance. It is interesting to note that the whole unit can be easily held up in the hands whilst running at over 2,000 revs. per minute. Whilst there are numerous points of doubt which one can raise, such as the position of the weight affecting stability (the inventor assures us that this is not felt when riding, any more than a touring kit on the carrier), yet it most certainly forms a very attractive addition to the pedal cycle. Particularly among those who, through advancing years, may be tired of pedal pushing on long journeys, it should find a ready sale when a return to normal business permits its manufacture.

A Tyre Mileage Cost Chart.

THE accompanying chart, which is being distributed by an American motor tyre manufacturer, is designed to show at a glance the cost of tyres per mile. If a thread be stretched across the chart, or a line drawn as A A, from the point on the left which indicates the cost of the tyre to the point showing the mileage on the right, it will cut the centre column at the point which gives the cost per mile.



A chart by means of which one may quickly find the actual cost of a tyre per mile.

For instance, if a tyre cost 15 dollars (£3 2s. 6d.), and ran 2,500 miles, the cost per mile is shown to be .6 cent (.3 pence); or again, a motor cycle tyre costs £2 1s. 7d. (10 dollars) and runs 8,000 miles, and the cost per mile will be approximately .06 pence (.12 cent). The chart being American is calculated for dollars and cents, but these are easily reduced to English coinage when it is remembered that a dollar equals fifty pence and a cent is the equivalent of a halfpenny.

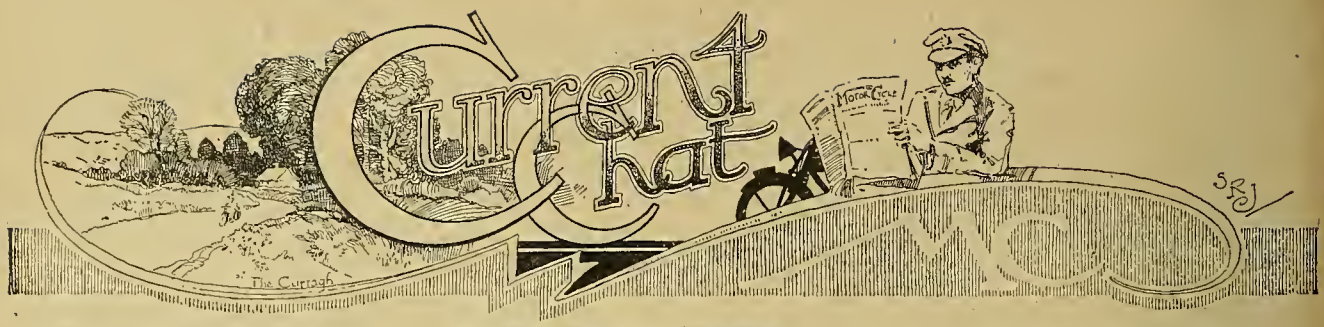
SENDING A MACHINE BY RAIL.

EVERY motor cyclist dislikes the expedient of sending his machine by rail, but it is one of those events which arrive, sooner or later in the unhappy lives of all of us.

When I am compelled to send my machine by rail I always turn to my old friend, the roll of insulation tape. By long application I have become an adept in the use of the "sticky roll," and my first act is to bind the change speed lever in the neutral position by means of a few dextrous turns. This habit I acquired by once watching a perspiring porter push a 6 h.p. A.J.S. the entire length of Birmingham Station with the back wheel skidding—owing to the fact that the gear lever had been knocked into the low gear position. The event was bad for the porter but worse for the tyre, and therefore I first make sure that no such Olympic feats will be necessary with my machines.

The next move is to bind the handle-bar control levers to the bars, for one of the commonest mishaps is for these levers to be knocked inwards or outwards beyond their extreme range, so that the machine finally arrives with the controls bent or broken. This hint was learnt by sad experience when, on one occasion, after a journey by rail, I had to "blind" through a long trial with the throttle lever snapped off short, and slowly but surely eating a hole through my glove and into my first finger.

If one has carefully "emptied" the tank with the machine on the stand, it may further be as well securely to bind the tap in the "off" position, so that danger of fire from a flooding carburetter, owing to the position of the machine in the van, is eliminated.—B.



TIMES TO LIGHT LAMPS

GREENWICH TIME.

Feb.	8	... ...	5.28 p.m.
,,	10	... ...	5.32 ,,
,,	12	... ...	5.36 ,,
,,	14	... ...	5.40 ,,

Trading with the Enemy.

A supplement to the *Board of Trade Journal* of February 1st contains a complete list of the names of firms which have been ordered by the Board of Trade to be wound up under the Trading with the Enemy Amendment Act, 1916.

British Magneto Factories.

Many of our readers would be much surprised at the enormous size of some of our new British magneto factories. One we recently visited is a veritable sky-scraper, employing many hundreds of hands and the finest scientific apparatus.

A Notable Appointment.

Mr. Wilfred Hill, a leader in the motor cycle world, and director of the County Chemical Co., Ltd., and the Calthorpe Motor Co., Ltd., has been appointed by Mr. Neville Chamberlain to an important post at the National Service headquarters.

Broken Frames in the Army.

Mr. Alfred Scott points out that it is estimated that 50% of the machines employed in France at any one time are out of action owing to frame breakage. Very often the smallest fracture necessitates a machine standing idle for many days, or may even necessitate its return to the factory of its origin. Mr. Scott tells us that one of the primary objects of his new frame (which we described in last week's issue) is to overcome this difficulty with regard to repairs. By his system a broken frame need not necessitate a delay of more than a few minutes

Club Premises Commandeered.

In a letter we have received from Mr. Arthur Stanley, chairman of the Royal Automobile Club, reference is made to unjust comments recently made in the press with regard to the taking over of the Royal Automobile Club by the Government. The representation that some of the members of the Club have, for their own comfort, endeavoured to oppose the commandeering of the Club premises is, writes the Chairman, contrary to truth. The letter refers to the valuable work done by the Club since the outbreak of war, and cites the fact that out of 16,000 members 11,000 are now in the Army or Navy.

Further Repair Work Impossible.

We have been requested by Messrs. Norton Motors, Ltd., to state that they much regret that, until further notice, they are unable to undertake further repairs to their machines, the whole of their plant and *personnel* being engaged upon work for the Ministry. In the meantime, however, they will be able to supply a limited number of spares.

The Russian Government and Overseas Models.

The specification laid down by the Russian Government has forced many British manufacturers to alter their designs in a way that will be truly beneficial to Overseas riders. Among other things an overall ground clearance of 6in. is stipulated, and many leading British manufacturers are now building their machines on lines which will put an end to most of the ancient Overseas grumbles.

What's the Price?

There was an amusing sequel to the first trial run of the small motor attachment for pedal cycles, which we describe on another page. An experimental model had been puffing merrily around the streets in the neighbourhood of its birth, and, be it whispered, without number plates, when shortly after the trial a police-constable walked with impressive dignity into the works. Naturally, those responsible anticipated trouble, especially when, in a firm voice, the gentleman in blue observed, "You've been running a motor about here this morning, haven't you?" The makers humbly acknowledged the fact, at which the constable brightened up. "May I have a look at it?" he enquired mildly. "It seems to be just the thing I'm wanting. What's the price of it?"

Prisoners of War for the Roads.

For a long time *The Motor Cycle* has advocated the employment of German prisoners for the rebuilding and repairing of our roads, once the pride of Europe, which have suffered so grievously through heavy traffic since the beginning of the war. We recently mentioned that prisoners are now at work on the roads, and the latest is that the Exeter Road is to be improved, and, in great part, rebuilt by German prisoners of war. Curiously enough, about a hundred years ago, at the time of the Napoleonic wars, French prisoners interned at the camp in Dorset were given a similar job to do, and made the magnificent stretch of road from Dorchester to Weymouth, with its remarkable avenues of chestnut trees, and also worked hard on the section of main road between Wareham and Bridport.

SPECIAL FEATURES:

SPRING SEAT PILLARS.
PROTECTION FROM MUD.
A MOTOR-ASSISTED BICYCLE
(Illustrated).

Skating.

Skating is seasonable, as we recently found out when trying to ride a big single on a certain famous stretch of the Great North Road. Contortionism may be a specialised business, but we surpassed all specialised efforts in an endeavour to maintain our equilibrium.

Some Skid!

Figure eights may be all right, but we touched eight hundred—the performance giving out only when we were compelled to clutch a telegraph post—not for support, but for breath. Some skid!

The Rink of Great Britain.

The Great North Road under the prevailing conditions is the rink of the land, but the motor cyclist to appreciate it needs to have roller skates attached to his footboards.

Lady Competition Rider's New Post.

Mrs. Hardee, secretary of the Woolwich M.C.C., has, we are told, accepted the situation of forewoman at a leading firm of motor cycle manufacturers. She will supervise the woman labour in one of the shops.

New Lighting Regulations.

We mentioned certain amendments in the lighting regulations last week. It is now permissible for cars to use electric or acetylene side lamps having lens fronts, in company with head lamps screened with tissue paper. Such side lamps must, however, be similarly screened.

The A.A. informs us that its booklets explaining the lighting regulations are being revised and brought up to date, and that copies may be had gratis on application to the head office, Fanum House, Whitcomb Street, E.C.

Common Courtesy.

There are many little courtesies of the road which it is to be feared a large number of motor cyclists are not very particular in observing. We have many times seen a rider pass a lady driver in traffic, and at a time when it was hardly courteous to take the liberty, though the rider may have every confidence in the safety of the procedure. Still, it is as well to remember that lady drivers may not be quite so confident as men, and an unexpected passing may have regrettable results.

The National War Funds.

At the week-end the principal war funds stood as follow :

The Prince of Wales's Fund (distributed £3,529,719)	£6,024,994	0	0
Red Cross Fund	6,107,990	13	3
Tobacco Fund	124,887	0	0

An Old Hotel Improved.

The Crown Hotel, Amersham, which used to supply *The Motor Cycle* teas to the competitors in the old Quarterly Trials, has been taken over by the Home Counties Public House Trust. It has been greatly improved internally, oak panelling had been discovered, and it has been refurnished and renovated.

Wild Life of the Waysides.

Truly the war penetrates to every scene of life, for country riders must have noticed the enormous increase of vermin since "the man of the gun" has taken to bullets instead of shot. We have recently seen hawks in veritable droves, while one can hardly take a ride over quiet country lanes without noticing one or more stoats or weasels.

Another Motor Cycle Theft.

A 1912 T.T. B.S.A. motor cycle was stolen from behind the Golf House, Belton Park, Grantham, on January 25th. The registration number of the machine is C 5462, the frame number 1,576, and the engine number 1,704. The machine is the property of Gunner W. Evers, Motor Battalion, M.G.C.

This is by no means the first theft that has taken place recently in localities where large bodies of men are assembled, and owners of machines will be wise to avoid unnecessary risk.

Re'arding Progress.

We have received a letter from Mr. Loughborough, secretary of the Auto Cycle Union, in which he sets forward the facts of a case which is of some interest and importance. A member of the Union was recently summoned to appear at the Kingsway Police Court charged with exceeding the speed limit and with contravention of the silencer regulations. To the first charge he pleaded guilty, but the second appears to have been founded on the fact that one of the police constables was able to poke his stick into the silencer, thus proving that it did not contain baffle plates. The silencer consisted of an unusually long expansion chamber, and Mr. Loughborough informed the Bench that, as proved in the silencer trials held by the Auto Cycle Union in 1913, the most efficient form of silencer was a long, plain expansion chamber, and that this type was now fitted to many leading makes of cars and motor cycles. Having had the machine driven before him at all speeds, Mr. Loughborough stated on oath that it was one of the quietest motor cycles he had heard, but the magistrates refused to hear the machine running themselves, so the motorist was fined, and his licence endorsed "For using cut-out, 10s."

Mr. Loughborough states that should any similar summons be issued in future he would be glad to be at once informed, in order that the A.C.U. may do everything possible to prevent a reading of the law in a manner which may tend to retard the progress of design.

The hard dry roads of the past fortnight suddenly gave place at the week-end to thick snow. But motor cyclists—particularly in munition areas—were not deterred by these conditions.

Lighting Restrictions on North-east Coast.

We have received from the hon. organising secretary of the North-eastern Automobile Association a copy of the Lighting Restriction map just published by that Association. The map, printed in pamphlet form, shows at a glance the necessary information.

Entertaining the Wounded.

Five hundred and sixty wonnded soldiers were entertained by the members of the Motor and Cycle Trades of Manchester District, who banded together as a result of a suggestion appearing in *Cooper's Vehicle Journal*. In addition to this hnge company, 140 men who could not leave their wards had their share of the repast sent to their wards. Many well-known artistes took part in the concert, and the event passed very merrily.

Lodge Plugs now Unobtainable.

Messrs. the Lodge Sparking Plug Co., Ltd., inform us that, in accordance with instructions received from His Majesty's Government, the whole output of the Lodge sparking plng factory has to be reserved for urgent national requirements. The company therefore regret that in fnture they will be unable to supply plugs (except for export) to orders unless accompanied by Munitions of War certificates, either Class A or Class B.

The Cycle and Motor Trades' Benevolent Fund.

At the monthly meeting of the Executive Committee, the Hon. Treasurer's report showed a balance at the bank and in hand of £2,881 13s. Since his last report, a further £2,000 had been placed in Government securities, bringing the total of the invested funds well over £25,000. During the past twelve months the Fund's assets have increased by over £4,000—testimony alike of the large-heartedness of the trade and the careful management of the committee.

Chars-a-bancs to be Dry Docked.

An Order was issued on Tnesday prohibiting the use of petrol or petrol substitutes in motor chars-à-bancs or similar vehicles on excursions or trips.

Motor Cycle Volunteers Wanted.

We are advised that a large number of motor cyclists are required by the National Motor Volunteers (London area). Applications should be made to the Commanding Officer, D. F. Doland, Room 5, The Polytechnic, 309, Regent Street, W.

A 1 h.p. Motor Attachment.

The motor attachment for pedal cycles illustrated and described in this issne will prove of particular interest to those pedal pushers who are advancing in age. Incidentally, it is not the only design of motor attachment on the *tapis*.

Manufacturers and the War Loan.

Messrs. Rudge-Whitworth have snbscribed £50,000, Messrs. Douglas Bros. £200,000, the Triumph Cycle Co., Ltd., £53,000 (£10,000 new money), and the Coventry Chain Co., Ltd., £25,000, to the War Loan

An Indian Club Affiliates.

We are informed by the secretary of the Auto Cycle Union that the Kirkee Motor Cycle Club (Poona, India) have applied for affiliation to the governing body. The club apparently is quite a live institution, and it is good news to hear of clubs affiliating in these strenuous times.

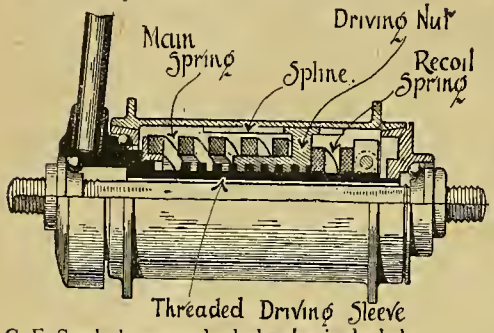
A Government Order.

New Imperial Cycles, Ltd., Imperial Works, Princip Street, Birmingham, have received a large order for 8 h.p. New Imperial motor cycles from the Ministry of Munitions, which will, for the present, very considerably restrict their output of New Imperial light tourist machines and other motor bicycles turned out by them.

AN INGENIOUS SPRING DRIVE.

WITH the usual type of spring shock absorber, the amount of movement of the driving element in relation to the driven element is small, with the result that very severe shocks are not completely damped out.

The construction here illustrated, which is the invention of Mr. G. E. Stanley (Patent No. 18,042/15), provides a considerable amount of relative movement between the driving element (which in the instance shown is a spoked belt pulley) and the driven element, *i.e.*, the hub shell. The belt pulley is carried on a long sleeve mounted on ball bearings on the wheel spindle, and the exterior of



G. E. Stanley's patent shock absorber in the hub.

this sleeve is formed with a coarse screw thread on which works a nut. The nut in turn engages splines in the hub shell, and on either side of the nut are arranged springs, the larger of which acts as the main cushion, whilst the smaller takes the recoil and comes into action when the cycle is driving the engine.

In operation, assuming the machine to be stationary, directly the belt pulley rotates, the driving nut first compresses the main spring until the resistance of this spring becomes greater than the load. Further screwing of the nut on the threaded sleeve therefore ceases, and the splined connection rotates the hub shell. Fluctuations in the driving effect and the load are therefore absorbed by the springs, and doubtless some of the power absorbed is given back to the nut when the action reverses.

The whole device is self-contained, and can be fitted and removed in just the same manner as an ordinary wheel hub.

AN ENDURANCE RUN IN INDIA.

MR PERCY JOHNSON, who is shown in the accompanying photograph on his H.-D. outfit, recently undertook a journey of 625 miles in seven days through the Bengal coalfields—not a record, but quite a worthy feat when heat and the inconvenience of Indian roads are taken into account.

Mr. Johnson, who drove the machine, with the native *mistri* as passenger, writes that "one morning an attempt was made to start out in a cyclone, but, being very nearly blown over a high and very long bridge, it was decided to rest that day." The run was undertaken in order to demonstrate to colliery managers and their staffs the possibilities of the motor cycle for covering long distances on all sorts of roads.

Frequently it was necessary to ride over quagmires and through water, and the trial appears to have been one of great severity.

Mr. Johnson was at one time connected with the advertisement department of *The Motor Cycle*.

EMPIRE OVERSEAS SIDECARS.

THE attention of Overseas readers may be called to one or two points additional to our article of last week (page 108) dealing with these special sidecars.

The bodies are built of metal under a patent (No. 26,867) process, which, it is claimed, renders them impervious to climatic conditions and capable of withstanding very rough usage. Another feature is the use throughout of castellated nuts fixed with cotter pins. This is a point often demanded by correspondents of *The Motor Cycle*, and is, incidentally, a part of the standard specification of the Russian Government, and we are glad to observe the increasing attention given to it.

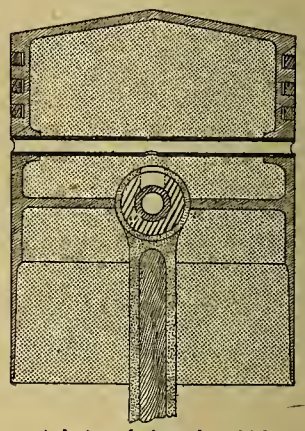
ROUNDED UP.

IN our issues of Dec. 14th and Jan. 18th we reported thefts cleverly carried out by a man in uniform wearing shoulder letters of the 7th Lancers—though no such regiment exists—and bearing, as reference, letters from his C.O. A clever ruse on the part of the police, alleged to be in the shape of an advertisement, brought this enterprising gentleman post haste into the arms of justice. Wearing the uniform of a trumpeter (says the *Daily Mail*) of the Lancers, from which he was said to be a deserter, Harry Moon was at Lambeth on the 31st ult. given six months' hard labour for stealing three motor cycles.

LUBRICATING THE GUDGEON PIN.

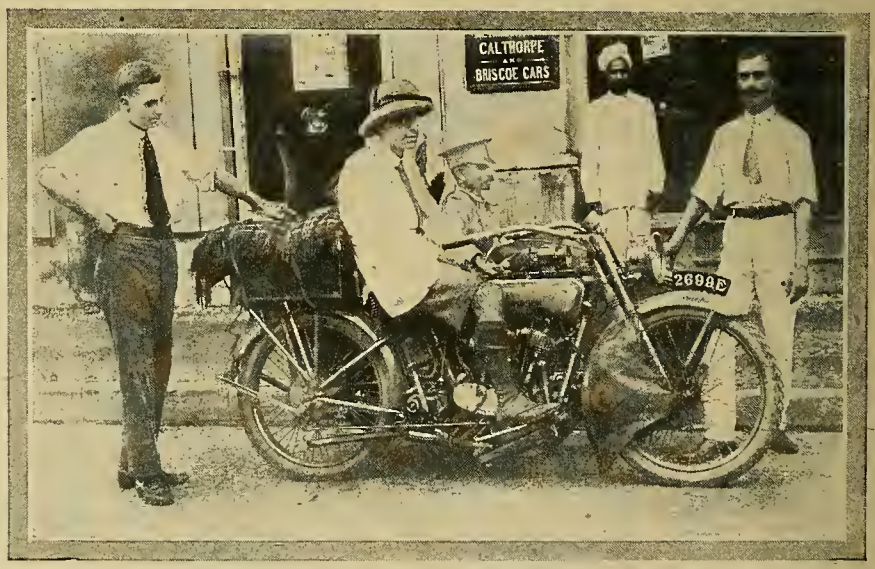
THE Albion Motor Car Co., Ltd., Scotstoun, have recently patented a new piston design, by which constant lubrication of the gudgeon pin is provided. From the accompanying drawing it will be seen that immediately above the gudgeon pin there is a small tube placed transversely across the piston, which is fixed by having its ends expanded or by other suitable means. Communication with the tube is by a groove round the circumference of the piston.

It is claimed that oil collects in this



A design of piston by which constant lubrication of the gudgeon pin is provided.

groove, and when the explosion of the charge takes place this oil is blown inwards through the tube and out through an orifice on the under side of the tube, which is directly over the small end and bush of the connecting rod in which an orifice allows oil to reach the gudgeon pin. Whilst the design reviewed is primarily intended for car engines, it would serve equally well for engines having the splash system of oiling.



Percy W. Johnson on a Harley-Davidson outfit on which he recently accomplished a tour of 625 miles round the Bengal coalfields. (See paragraph.)

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

EASY STARTING ON COLD MORNINGS.

Sir,—In the Arctic weather we have had here (Dublin), I have found some trouble in starting a 5-6 h.p. twin. Since trying a tip I saw some time ago, I start first kick with ten degrees of frost. The tip is to use a mixture of methylated ether and petrol in equal parts and prime cylinders with this. Very little does, and it is worth the cost (about threepence or fourpence an ounce). This tip does not seem to be well known. R. L. BOYD.

[This tip has frequently been mentioned in our pages by "Ixion" and others.—ED.]

COMMENTS ON THE POST-WAR MATCHLESS.

Sir,—In recent issues of *The Motor Cycle* illustrations with some details have been given of the "post-war Matchless." I was very interested in the description, and it seems to me that this is, as far as I know, the first (perhaps there are other makers who have not yet announced their plans) British-made machine which can be considered to go one ahead of the Yankee article, and should command a large sale. It has many features about which a large number of home and Overseas readers have continually written to your paper, to mention, amongst other points, spring frame, efficient mudguards, 3in. tyres, powerful flat twin engine, mechanical lubrication, totally enclosed chain drive, enclosed valve springs, quickly detachable interchangeable wheels. I would like to make a remark on the machine, and that refers to the type of handle-bars, which appear to be very much like those shown in fig. 1, page 48 of your issue of January 18th, whereas, according to the article in question, it would be better if the handle-bars were of the semi-T.T. kind, as per fig. 2.

I would like to end by saying that I presume the difficulties mentioned in the article by Mr. Eric Williams, in the issue of the paper just mentioned, with reference to getting at the magneto, are overcome in the new Matchless.

London, S.W. A.M.I.E.E.

THE FLAT TWIN AT THE BAR.

Sir,—I have read Mr. Osborne de Lissa's further letter in your issue of January 25th very carefully, and still fail to find anything of practical interest, technically or otherwise, to motor cyclists. In fact, his whole endeavour appears to be a personal attack on the engine of my design, and principally on account of the progressive aims of the design. His statement that he likes to leave out technicalities, and that he has not found it necessary to impress technical knowledge upon everyone, confirms this. My impression is that one must either discuss technicalities or personalities, and I venture to suggest that the motor cyclist is interested enough in his hobby to prefer the technicalities. Mr. de Lissa thinks otherwise, therefore I may be wrong, but I am open to correction on this point.

Mr. de Lissa then proceeds to remark on the improved cooling, smoothness, lack of vibration, capacity for continuous heavy duty, and correct and regular oiling, which I stated were the aims of the A.B.C., but he still fails to explain technically or practically wherein these aims are wrong.

For instance, with regard to cooling he says: "From what I can gather the A.B.C. has nothing exceptional in this respect." All I can add is that he has gathered very little that is truthful, and personally I should be very diffident about making such remarks as he makes on mere hearsay, and without having a more intimate knowledge of my subject.

On the subject of vibration, he says that other horizontal twins with which he has had experience are equally vibrationless as the A.B.C. To this I can only add that either he has had no experience of the A.B.C. whatever, or else that he has not gone to the trouble of making a comparative test.

Personally I have made a very careful test of a modern M.A.G. engine, covering a distance of between four and five thousand miles, and in the light of such test I can only state that Mr. de Lissa is very gravely misinformed when he states that the M.A.G. engine will hold its own against any engine in the world in perfect smoothness.

Despite my assurances, Mr. de Lissa reiterates his suggestion that the A.B.C. engine causes burnt-up plugs, and this leaves me no alternative but to suggest that he produce a M.A.G. engine with any sparking plug he likes to name; we will run a duration test on identical plugs under identical conditions, and the results shall be published in *The Motor Cycle*. GRANVILLE E. BRADSHAW.

Sir,—I am afraid I cannot possibly keep out of the controversy between Mr. Bradshaw and Mr. de Lissa any longer. I am sorry to see Mr. de Lissa "snapping" as he is doing. I am equally sorry to see the letter of "A.M.I.E.E.," of Wimbledon Park. From it, it would appear that he is unable to discern "the pigeon in the flock of rooks." It would be equally sensible to say that, because Casement was a traitor all his countrymen are, too.

But to come to the question of flat *v.* V twins, I regret it has not been my pleasure to have a long fast run on an A.B.C., and so I must perforce confine my remarks to the Douglas. On several occasions it has been necessary for me to get from London to the North Wales district in a short time without much preparation. These journeys have been made on two types of machines—one, the flat twin, was a 2¾ h.p. Douglas, and the other a 3½ h.p. Motosacoche, which was fitted with Mr. de Lissa's patent air-cooled exhaust valve. My experiences showed me that it was impossible to let the flat Douglas all out for more than a mile,* and even then it took some time to recover itself, whereas the Motosacoche with the V M.A.G. twin, plus the air-cooled valve, could be let out full for as long as the road and rider would permit. (I do not wish it to be understood from these remarks that I took risks by "blinding" through villages, but I think most people know the long stretches of Watling Street dead straight and not a soul in sight.) From this I necessarily "plump" for the M.A.G. engine V twin for fast solo work. I have also had long runs with a sidecar both with a big flat twin and a big V twin, and for some reason the V twin seems to give far and away the better pull on a stiff hill after a twenty-mile run. I am not prejudiced in any way against the flat twin, and, in fact, I prefer it both for solo and sidecar work in town traffic, but when it comes to the open road I want a V twin every time.

S. Farnborough, Hants. LITTLE JOHN.

[*We would refer "Little John" to the results of the last Junior T.T.—ED.]

BEARING PRESSURES AND LENGTH OF STROKE.

Sir,—May I butt in *re* the article by "A.A.S." on bearing pressures?

He makes one very great error in *adding* the explosion pressure on the piston to the inertia force of the piston to arrive at the resultant pressure on the gudgeon pin at the moment of explosion. Obviously, the inertia force is upward and the explosion pressure downward, and the resultant pressure is the *difference* between these two forces and not

the sum of them. He also omits entirely the centrifugal force of the big end and lower part of the connecting rod in arriving at his big end pressures. This force, in addition to the inertia of the piston, has to be deducted from the explosion pressure to give the actual big end load.

I do not think that any of your contributors on the "Long *v.* Medium Stroke Engine" have gone deeply enough into the dynamic forces at work in a high-speed engine, and hence none of the arguments put forward are quite conclusive. The study of these forces entails some considerable work, but I hope shortly to complete an exhaustive analysis of all forces at work in two engines of similar capacities but different stroke-bore ratios. CHAS. K. EDWARDS.

WHO SHOULD HOLD DRIVING LICENCES?

Sir,—I think it grossly unfair that such a step as mentioned in *The Motor Cycle* for February 1st should be taken.

I suffer from slight deafness myself, but I do not find it interferes with my driving in the least, neither do I consider this affliction causes the least danger to the public. I always drive carefully and at moderate speeds.

Let the Northamptonshire Committee save the lives of the public by all means, but let it first find out the total number of accidents in the United Kingdom, say, for one year, and pick out those that are due to *deaf drivers*. I venture to say that most of the serious accidents are caused by "the road hogs," who continnally break the laws of the road, and who think that once their horn is sounded other motorists can go into the ditch before they will throttle down to anything like 30 m.p.h. Many a time I have been obliged to steer on to the grass at the side of the Great North Road in order to allow a car to dash between me and another vehicle. BERTHA A. ANDREAE.

Sir,—I entirely agree with the action of the Northamptonshire Licences Committee in urging that no licences should be granted to blind or deaf (or partly deaf) motor drivers. No sane man conld act otherwise, as it is obvious that on very many occasions the sonnd of a horn is the only thing that prevents a collision. If this is not so, why fit horns on motors at all?

However carefully a deaf driver drives there are many occasions on which he is bound to come to grief, if he cannot hear a warning note, whether a shout or blast of a horn. Again, what about runaway horses? A runaway on a winding road can he *heard* far away by a driver of average hearing capacity, and he can draw into the side of the road and thus avoid a smash. If deaf he will cheerfully keep in the middle of the road until he *sees* the runaway, when it will be too late. It is quite true that a reckless driver is *also* a source of danger, however good his eyesight or hearing may be. My experience of some five years on the road has shown me that a good 75% of motor cycle and car drivers should not be granted licences at all. Hardly a day passes without meeting some driver who drives full speed down a side turning into or across a main road, and often without ever troubling to sound his horn! In winding lanes, too, I am constantly meeting cars and cycles, the drivers of which never sound a horn, and, were it not that I always do so, there would be a smash every time. Whenever a driver cannot see more than, say, fifty yards ahead he should blow his horn, and failure to do so should render him liable to a stiff fine, £5 at least.

Our laws with regard to regulation of traffic are certainly a disgrace to a civilised nation. While we have absurd regulations with regard to dimming lights at night "in the interests of public safety," we bave no regulations against foot passengers walking in the centre of the road, or against the granting of licences to incapable drivers, both of which cause far more loss of life every year than could occur through a motor carrying the most powerful "searchlights."

No licence for driving a motor car or cycle should ever be granted without a preliminary test of eyesight, hearing, and "general intelligence." M. HITCHCOCK.

Sir,—I see in last week's number of your valuable paper that the Northamptonshire Licences Committee is making a representation to the Home Office urging that licences should not be granted to persons suffering from blindness, etc. May I ask what is meant by "blindness"?

I have lost my right eye and left leg as a result of wounds received in France, and some months ago bought a motor cycle and sidecar to enable me to get about better. I hope that there is no likelihood of people disabled as I am being refused licences, and, if there is, that *The Motor Cycle* will combat any such suggestion.

I have no foot controls on the left side, and as the sight of my one eye is very good, see no reason why I, or others like me, should be considered incompetent. M.C.S.

CAM DESIGN.

Sir,—*Apropos* of the article on cams, in your issue of February 1st, I should like to point out an error which "A.A.S." will, I think, agree that he has overlooked.

In his plan of construction for obtaining the contour of the cam, he has omitted to take into account the effect the curve of the roller has upon it.

In fig. 1 I give the correct construction, which shows a very different contour from that obtained by "A.A.S."—as shown in fig. 2, for comparison.

In these examples I have taken the case of harmonic motion, and have made every part of the same proportion as those given in his article.

The difference of the two constructions lies in the marking off of the actual points on the contour from those obtained by the intersection of the radii and the arcs. This should be done by drawing a succession of arms of radius

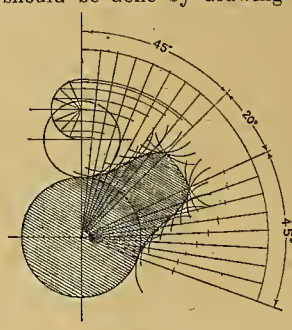


FIG. 1.
CORRECT CONSTRUCTION.

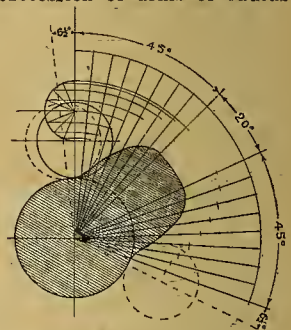

FIG. 2.
INCORRECT CONSTRUCTION.

equal to that of the roller, and with centres at the points of intersection just mentioned.

The true contour of the cam is then obtained by drawing a continuous curve tangential to these successions of arcs.

"A.A.S." has apparently merely stepped off distances on the radii equal to that of the radius of the roller. The curve of the contour obtained in this way would not impart harmonic motion to the valve. At the same time, it would cause the valve to remain open through a larger angle than he intends it to do. I have drawn in dotted lines (see fig. 2) the position of the roller—relative to the cam—when the valve would be on the point of opening and closing. In the example he has taken, it will be seen that the valve would open 6½° earlier and close 6½° later, giving a net opening of 123° instead of the intended 110°.

N.B.—The construction I have just shown is only strictly correct for rollers which are pivoted directly on to the tappet, *i.e.*, rollers which are confined to movement in a straight line radial to the centre of the cam (as taken by "A.A.S.") Rollers pivoted on to the end of a rocker would necessitate a more complicated construction.

E. R. GREEN.

HEATING THE INDUCTION PIPE.

Sir,—My twelfth and present mount is a 3½ h.p. overhead H.T.T. Brough, and as an experiment in tuning I "completely exhanst-jacketed the induction pipe."

For Capt. Lindsay's satisfaction I append the results, culled from a notebook my brother and I own, with all details of our machines, tunings, results, and expenses entered in it.

"Shoved a complete copper jacket on induction pipe of 'Mark I.' (my machine), led small copper tnbe from the front exhaust to the jacket, and sweated all joints.

"Mark I. now accelerates much qnicker than Mark II., and does at least twenty more miles to the gallon."

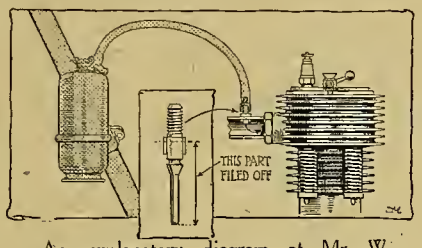
The second machine (my brother's) has now been fitted the same way, and doubtless, should I perpetrate the crime of taking leave soon, some new development will transpire.

JOHN HAWES.

STARTING ON ACETYLENE.

Sir,—I see in your issue of January 18th an article on "Starting on Acetylene." The idea is not new, as I used the same thing in the latter part of 1913, but gave it up as there is a great danger of the cylinder head being blown off through the explosion of the acetylene gas.

I bored a hole in the induction pipe and fitted an ordinary tyre valve. The sketch will explain how this was done. The bottom part of the valve was filed off, and the top part was pushed up through the induction pipe and secured by the dust cap (blind end filed off), which acted as a lock nut to hold the valve firmly in place.



An explanatory diagram of Mr. W McLean's device for starting on acetylene. (See letter.)

It was coupled to my P. and H. generator on the down tube by the foot pump connection. One end was screwed on the valve and the other screwed end was cut off so as to get the rubber to slip on the gas exit of the generator. I also fitted similar valves to two chums' motor cycles, and they, too, gave them a test, and have since discarded them. The fitting of the jet is a very simple job indeed, and need cost no one anything but the slight labour of boring. I note it is stated in a contemporary that the device is fully patented. It certainly starts an engine when using paraffin as a fuel, but give me petrol and I will leave acetylene gas alone. I never used it with paraffin, but I often did with naphtha as a fuel. The explosions were pretty violent, and would soon have played havoc with my 3½ h.p. Premier. My chums used it on a 1914 Humber and a 1915 Imperial-Jap. The heat, too, was considerable, more so than with petrol, and perhaps this is why paraffin gets vaporised so easily. It would be interesting to know the state of the bearings after prolonged use. I suffered a broken ball bearing on the timing side and a cracked piston. One has to be very careful with the spark lever, as a backfire with acetylene is a thing to be guarded against, especially when starting up.

Perhaps Mr. Passey will write and let us know what the engine bearings of the B.S.A. are like after 5,000 miles, and if he finds much deposit on his piston after, say, 1,000. I have tried all sorts of fuels—paraffin mixed with petrol, naphtha, benzole, acetylene and naphtha, and petrol substitute. Paraffin and petrol combined caused knocking on hills and a slight loss of power. Hot air pipes to the carburetter improved matters a great deal. Naphtha produced the same results, or nearly so. Benzole is the goods. When the war is over and the Government releases the benzole for public use I will use nothing else. This is the fuel of the future, I believe. Certainly my tank was destroyed by it, but I will have a special tank made for that fuel. Acetylene and naphtha give plenty of power, but considerable heat and knocking on hills if the spark be kept fully advanced. I discontinued its use because of breakages inside the engine and the danger of a burst cylinder owing to the violent explosion. Petrol substitute. Ugh! I must have got hold of a bad brand of it. "Na-poo." No matter what fuel you use, if you apply heat to the carburetter you will get far better results. With my 3½ h.p. Premier and heavy sidecar I could average 88 m.p.g. over the hilly roads of Fife after fitting hot air pipes to the carburetter. When on a week's tour last August the outfit was loaded up so heavily that my passenger (11½ stone) had to lie on the top of the sidecar with his feet over the front. I myself am nearly 12 stone, and the hills were a good length, which caused us to run for a considerable distance on low gear, and yet 88 m.p.g. was our average over seven days' running. The carburetter was a 1913 B. and B. single-jet model, jet No. 32. All the air was heated before entering the carburetter. My chum averaged 96 m.p.g. with a Humber. It had a B. and B. with a variable jet, and had also hot air pipes. His outfit carried a camp army bell tent and all utensils. So for economy and power *heat the carburetter*, no matter what fuel you use.

WILLIAM McLEAN.

INVENTIONS.

Sir,—I notice in last week's issue of *The Motor Cycle* a new Bowden wire nipple, and that it is the invention of one of Messrs. H. Taylor and Co.'s mechanics. With all due respect to the mechanic claiming to be the inventor, I wish to point out that the same idea was invented over forty years ago, and used on all the Willcox and Gibbs hand machine needle bars to secure the needle. If the mechanic in question has not seen one, he can do so at the firm's depot in London. No doubt he will be able to find out where there is one.

I, like a good many other mechanics, have invented things, but have never been able to bring them to the front. I might just mention that I made during my apprenticeship a brass spinning top that would spin for half an hour; I have one now in my possession that will spin for twenty-four minutes.

WM. BEECH.

PUSHING MOTOR CYCLES.

Sir,—As a medical practitioner of thirty years standing and a reader of your paper since 1904, I have been much interested in reading "The Hygiene of Motor Cycling."

I gave up pushing my own machine in 1910, when Messrs. Douglas Bros. fitted one of their first two-speed gears. I also gave up pedals at the same time.

Some of your readers may remember that I asked in your columns in 1906 that we medical practitioners who used our machines for professional purposes might be supplied with three improvements—

1. Multiple speeds.
2. Low-built machines.
3. Efficient mudguarding, with proper clearance between wheels and mudguards.

When these three are obtained there is no reason why, if the necessary spares are carried, any motor cycle should be pushed.

Since my letter of 1906 was written I have had over 100,000 miles of road experience by motor cycle, not one-tenth of which was over main roads, and much of it over downs and field tracks.

I have come to the conclusion that, in spite of the drawbacks of war time (such as no skilled labour and the impossibility of obtaining spares and necessary replacements), the motor cyclist who requires to push his machine is, as a rule, either not properly provided with spare parts, careless as to the condition of the machine, or not properly acquainted with the mechanism. He may, for his sins, be riding one of the very imperfect models which still somehow seem to survive in small numbers.

An interesting commentary on your articles appears in *The Referee* of January 28th, under "Aviation and Motoring." The writer points out that the Army is training motor cycle despatch riders to get them fit so that they could push their machines. How pitiful! And how likely to break down the really efficient brainy lightweight who, from his knowledge and resourcefulness, is invaluable for work which of necessity is a one-man job.

I know and have conversed with dozens of Army motor cyclists, many of whom I had met over competition work in the past, and have seen something of military motor cyclists' training, and can write from personal knowledge.

Motor cyclist expert knowledge seems to be lacking among the higher officers in any Army department where motor cycles are used, such as the R.F.C., A.S.C., Signals R.E., R.N.A.S., etc. Even the officer occupying the same position as the veterinary officer to a cavalry regiment, though excellent as a soldier and a gentleman, has little or no practical knowledge of the machines.

As regards non-commissioned officers, many are experts, but are these to obey orders issued by gentlemen who know little or nothing about the mechanism with which they are working?

If the men with a thorough knowledge of motor cycles now scattered hither and thither throughout the Imperial Forces were put in command of motor cycle units and in supervision of factories at home we would rapidly find the right machines going to the Front, the right men riding them, the right men being trained at home to take their places, and thus training would be conducted in the quickest and most efficient manner.

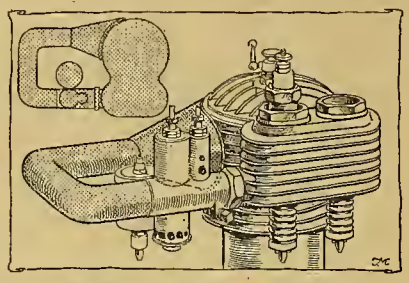
May we get efficiency before it is too late.

CHARLES S. PATTERSON, M.B., M.R.C.S.,
Late Judge Auto Cycle Union.

HEATING THE CARBURETTER.

Sir,—I was interested in H. H. Brownrigg's letter in *The Motor Cycle* of January 18th. It has frequently been stated that a hot air intake makes for better running and petrol economy. With this in view, I fitted on to my 3½ h.p. Sunbeam a Binks carburetter having a hot air intake, but with the addition of a wide bell mouth.

I tested it last November, when the weather was fairly warm. I ran without the hot air intake twenty miles by the speedometer at 25 m.p.h., and used one and three-fifth pints of Shell No. 2, carefully measured. I waited three hours, attached the hot air intake, and did the same run at the same speed, with the same result, *i.e.*, 100 m.p.g.



Another device for heating the carburetter. (See letter from M.A., LL.B., M.B.)

I have noticed that the whole of the hot air intake gets quite warm right round to and including the carburetter within a few miles of starting. Further, I found the engine knocked more than it had previously. In the recent cold weather the hot air intake does not get so warm, and the knocking is less.

I have not had time for further experiment, and would like to hear from anyone who has actually tried whether a hot air intake does economise petrol. It is necessary for paraffin. M.A., LL.B., M.B.

Bury St. Edmunds.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—I always read with great interest your paper, which has already done so much good for the motor cycling cause, and notice in *The Motor Cycle* of February 1st a letter from Mr. S. Barker, in which he praises up his American motor cycle. He states that our British makers "will stick in a groove," and talks about the refinements and wonderful reliability of his machine. We all know that the Harley-Davidson is a good machine, but I venture to think that English makers holding a similar position in this country are able to make machines with certainly equal if not greater reliability and refinements than the Harley-Davidson. I wonder if Mr. Barker has ever tried a Sunbeam, an A.J.S., or a Zenith. If he has tried any of these and still prefers the American machine, all I can say is there is no accounting for tastes. If he has not tried any of them, then I do not think he has any right to criticise English manufacturers as a whole. Personally, I prefer to buy English to American goods provided one gets value for the money.

The usual disclaimers. C.A.L.

Hengrave.

Sir,—I know little of motor cycles, but ignorance is nowadays no excuse for silence. I may, however, claim to be interested in every way except financially, and I wish to shout with the crowd of those who prophesy the early decease of the single-cylinder.

For two months last summer I did a great deal of motoring on a 3½ h.p. and sidecar, having one cylinder and a much quoted name for excellence. It was simple, reliable, cheap to run, and reasonably fast, on the level at least. But the vibration was horrible, and neither specialist engineers nor my own experience with cars could induce it to run slowly when not under load. These faults were so glaring that they quite outweighed any merits.

This will surely not do. Cars have long outgrown such monstrous defects, and such a jerky type of engine. They will never return to it; machinery is not atavistic. Why should it survive on motor cycles? May its time, for the sake of all suffering riders, be short.

Most of the apologies for the single-cylinder that I have read reduce themselves to one plea—simplicity. Now simplicity is not a virtue in itself and by itself in engineering any more than in other things. If complication gives better service, simplicity must go. So it has been with cars, where the same arguments served as funeral orations for what they were defending; so it will be with motor cycles, if it is not so already. All cars nowadays have four cylinders (save those which have six or eight), even in the smallest size and power. Though four may be too many for a motor cycle, owing to restrictions of space—from all accounts the flat twin is an excellent substitute—one cylinder is most certainly too few.

The single-cylinder has shown the way, but, partly for that very reason, it cannot follow it further. To pioneers all credit is due; but when the land is settled and cultivated, none but the sentimentalists regret the conditions of the pioneers. M.E.I.

The Hague.

Sir,—In *The Motor Cycle* dated January 18th, 1917, "Ixion" expresses his surprise that no rider of the big twin has written upholding the merits of this particular kind of mount.

At the present moment I am the possessor of an 8 h.p. single-speed overhead valve Matchless-Jap. I find it an exceedingly pleasant mount to ride, and not a vibrating monster, as so many enthusiastic riders of flat twins would have us believe. It is exceptionally easy to start, three or four yards at a sharp walking pace never failing to start it even from cold.

One of the objections raised against big twins is their great weight. My Matchless is very light, somewhere in the region of 200 lb.; perhaps this is on account of the absence of a gear box. I presume it is unnecessary for me to dwell on the speed and power of such a mount.

I am of the opinion that such a machine fitted with a variable pulley, such as the Philipson, would be a very pleasant touring mount.

R. C. M. KERMODE.

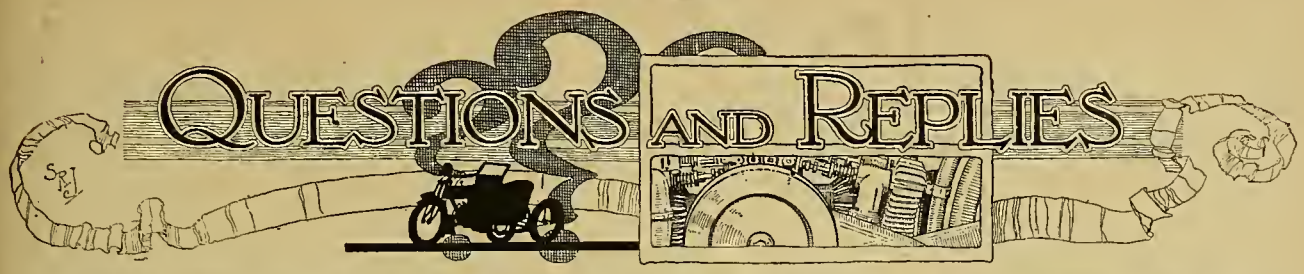
Sir,—Allow me to thank your correspondent "H.K.P." for his exceptionally pleasant remarks regarding the efforts I have made in my numerous letters and contributions to your journal to help your readers.

I am also very interested to read Capt. A. Lindsay's further letter, and now quite agree that we are not at variance on the subject of induction pipe design. I am quite willing to admit that the single-cylinder vertical engine is a much easier proposition from the induction pipe point of view, and that, in order to obtain the numerous advantages of having a flat twin engine, the designer must pay much closer attention to the induction pipe on such an engine; but this, in any case, is not really a difficult matter.

With regard to Capt. Lindsay's paragraph, "Can an engine be said to be uniformly cooled when two such dissimilar temperatures can exist 6in. apart in a mass of metal under running conditions?" I am sorry I misconstrued his contention in the first rendering of the same paragraph, which is, as a matter of fact, the crux of the whole problem in air-cooled cylinder design. It is physically impossible in engine design as we know it to-day to maintain an even temperature in the whole mass of metal comprising the cylinder and its adjacent parts. The inlet is cool and the exhaust is very hot. It does not affect the inlet port if the carburetter is placed further away and becomes excessively cold, and the question of carburetter heating and long induction pipe is a totally different one from that of uneven temperatures in the cylinder itself. What *does* matter is the effect this difference in temperature in the cylinder may have upon the rotundity of the bore and the temperature of that part in contact with the pistons, and the principal thing left to the designer is to arrange these in such a manner that they are least detrimental to the life and efficiency of the working parts of the engine. The arrangement I have adopted is to place the exhaust valve overhead, and to insulate this against close contact with the cylinder walls by interposing the cool induction passage, and I have found that very little experiment is required in order to balance up the heating almost exactly.

With regard to Capt. Lindsay's suggestion of completely exhaust-jacketing the induction pipe of a flat twin engine, there is no reason at all why this should not be done, and an induction pipe of such design was used by Emerson on the track. A little care has to be exercised in the construction of such a pipe in order to prevent it cracking through the exhaust jacket being very hot and expanding to a greater extent than the cooler induction pipe.

GRANVILLE E. BRADSHAW.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Naphthalene Balls in Fuel.

May I ask your advice with regard to the use of naphthalene balls in motor fuel? Are they likely to have an injurious effect upon the engine, and are they likely to give any increase in mileage per gallon?—L.G.M.

We do not think that naphthalene balls can possibly have any injurious effect upon a motor cycle engine. Some of our readers claim to have found that they give a marked improvement both as regards running and in the matter of carbon deposit. A Faraday House test has shown that the extra mileage is not likely to be more than 0.5%, and where any large increase is discovered it is probable that other circumstances have affected the result to some extent.

Clutch will not Disengage.

The clutch of my Sturmey-Archer three-speed hub is so tight that no adjustment which I can make will render the engine free enough for me to start it with the wheels on the ground. I always find it necessary to put the machine on the stand to start the engine. The operating rod did not appear to be long enough, for when it was pushed in so that its end was flush with the end of the axle the engine was not free, so I fitted a slightly longer rod and adjusted the operating screw. This gave some freedom, but it is still impossible to start the engine with the back wheel on the road. Can I remedy this by removing one or more of the clutch plates? I had new plates fitted some months ago, and it is only since then that this trouble has occurred. If removing the plates will cure the trouble, please tell me how this must be done.—E.McC.

Although removing one of the plates may free the clutch, we do not think this should be necessary. According to the detailed instructions for fitting and adjusting a Sturmey-Archer three-speed hub gear, published by Sturmey-Archer Gears, Ltd., failure to release the clutch is due to too slack an adjustment of the clutch rod and bad operating position of the clutch worm arm. The clutch worm may project too far over the axle end, or the clutch pedal tube may not be held securely from revolving. It is quite possible that the stiffness is due to the oil used for lubrication being too thick. Try washing the clutch out with paraffin and oiling with thin oil. You may have been using a wrong grade of oil, which has lost its lubricating qualities and merely gummed up the plates.

Motor Cycle Speed.

As a result of discussion with a fellow D.R. I am writing to ask if you will kindly supply me with details of the world's record speed attained by motor cycle?—F.P.J.

In England the highest speed officially attained by a motor cycle is nearly 93 m.p.h., by Sidney George, on an eight valve 7 h.p. Indian on Brooklands. In America and Australia speeds exceeding 100 m.p.h. are claimed to have been made, the highest being by Jack Booth, who in Australia, on the Gawler Road, covered a mile in 35s., which equals a speed of just under 103 miles per hour. His mount was also an eight valve 7 h.p. Indian.

Decarbonising.

I have been running my 4½ h.p. B.S.A. combination on paraffin after having fitted a hot air intake, an exhaust jacketed induction pipe, and after taking the fuel feed pipe once round the cylinder head, and have found these arrangements perfectly satisfactory until the engine becomes carbonised, when knocking begins. This takes place after about 500 miles or so, and is put right only by decarbonising in the ordinary way. I note that a chemical decarboniser exists for mixing with the lubricant to keep the engine free from deposit, and shall be glad if you can tell me (1) Whether it would be suitable for my purpose, and would prevent my having to take the engine down every 500 miles? (2.) Can it do any harm to the engine?—A.M.I.E.E.

(1.) We do not think that such a preparation would have very much effect. (2.) The only satisfactory way of avoiding taking down the engine every four or five hundred miles is to get it decarbonised by the oxygen process. The knocking you complain of might be considerably reduced if the compression were reduced slightly.

DELAYS IN POSTAL DELIVERIES.

In view of depleted staffs, the curtailment of railway services, and the consequent delay in delivery of mails, readers will greatly assist by forwarding communications (including advertisements) as much as possible in advance of the dates of the issues for which they are intended.

Reducing Tyre Troubles.

Since I cannot carry a spare wheel, what is the best method of ensuring freedom from puncture in the driving wheel? I often have to ride at night and in the wet, and therefore wish to take every precaution to avoid tyre trouble. Is it advisable to have tyres retreaded as soon as the pattern has worn down? Does a retreaded tyre behave as well as a new tyre in resisting puncture?—E.E.

The only way is to use as heavy a tyre as you can, or to fit an inside liner, obtainable from the principal accessory dealers. Nail catchers made of stout wire, or a piece of metal bent to the contour of the tyre tread and fixed to some part of the machine so that the tyre runs as closely as possible to it, may help to prevent punctures due to nails. It is not advisable to have tyres retreaded unless the retreads are intended to be used on the front wheel or sidecar wheel. A retreaded tyre may behave as a new one in resisting punctures, but it also may burst owing to an unnoticed weakness in the walls or tread.

Two-stroke Rattle.

I have a 2½ h.p. two-stroke which I carry to sea with me. Recently it has developed a rattling noise, similar to that of drawing a stick rapidly along a corrugated iron hoarding. This noise is only perceptible when I lift the compression release valve. I have the engine taken down at the moment of writing, but I do not see any signs of a slack bearing; there is just a little side play in both the crank and main bearings, but I take it this is quite usual.—Lt., R.N.R.

The rattling noise you complain of is a very common trouble with small two-strokes, and is one of those problems which has never been really satisfactorily solved, one rider claiming to have cured it one way, while another gives a totally different treatment. We would advise you to look at all the following points: Remove all carbon deposit very carefully from both cylinder and piston, also from behind the piston rings. Make sure there is no up and down play in any of the bearings; side play does not matter. Use a good plug with stout electrodes which will not become incandescent and cause pre-ignition. See that the exhaust outlet is perfectly free. You will probably find that after a careful clean out the noise will cease—at any rate for a time.

Lady's Motor Cycle.

[?] Will you please give me advice on the following points with regard to buying a motor cycle for use by a lady who is an expert cyclist, but has never before ridden a motor cycle? Would you recommend: (1.) A second-hand machine to begin with or a new one? (2.) A gentleman's model or one specially built for a lady?—F.R.

(1.) It is always preferable to buy a new machine if possible, as second-hand machines usually have had the best running taken out of them. A couple of trial runs on a second-hand should suffice to prevent ill usage of the new mount. (2.) Whether a lady's or gentleman's model is chosen is entirely a matter of personal taste. A lady's model is probably more convenient, as the rider would not be quite so restricted as to the choice of dress.

Valve Timing.

[?] I should be greatly obliged if you would let me know in as plain words as possible how I could time the valves of my 3½ h.p. single; also the ignition timing.—D.F.

You will find the following valve timing quite satisfactory for all-round touring: Exhaust valve closes when the piston reaches dead top of stroke, inlet opens immediately after; leave the opening of exhaust and closing of inlet to the design of the cams. If the inlet and exhaust cams are both mounted on the same gear, time the exhaust valve as directed above; the other settings will then be automatically correct. The spark should be timed to occur as early as possible without causing knocking; try setting it as follows, and if not right it can be moved in either direction as the running indicates to be necessary: Piston top of stroke (that is, one complete revolution after exhaust has closed), contact breaker half advanced, contact points just about to break.

Whose Fault was it?

[?] Would you kindly let me know who was in the wrong in the case of an accident which I am about to describe. I had just started my motor cycle and had got about 100 yards up a hill, and was on the left-hand side of the road, when I saw a coal cart on the extreme right-hand side. I did not sound my horn, but my engine was making plenty of noise, and as it was impossible for even a pedal cycle to get round on the right-hand side, I tried to go by on the extreme left. Then the man driving the coal cart, without holding his hand out or making any sign whatever, turned his horse round in the road right into me. Had I gone on I should have struck the horse. I tried to turn, but it being too sharp an angle and too greasy a road I went over. Then the driver finished turning round and went off shouting out something about it being my fault. I broke six spokes in the back wheel, bent the mudguards, broke a pedal and bent a crank, but did not hurt myself, so I was fortunate. I was travelling at about ten miles an hour.—K.M.S.

You were clearly in the wrong. In nine cases out of ten you might have got through safely, but this does not exonerate you. If the matter were brought up before any court the magistrate would say that if you were in doubt you should have stopped and waited. You were also in the wrong in not giving warning of your approach. The noise of your engine does not count as "audible and sufficient warning," and if it makes too much noise in the opinion of a police constable you may be prosecuted. The driver of the cart should, of course, have indicated that he was about to turn, but he was not under any legal obligation to do so, while the law says the driver of a motor car or motor cycle must give warning of his approach.

READERS' REPLIES.

Misfiring.

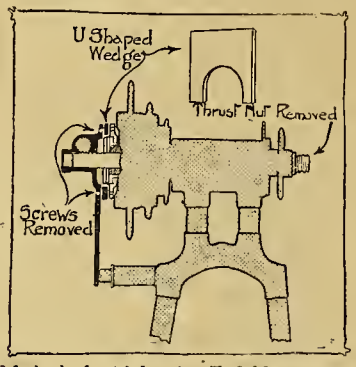
Re your reply to "T.B." concerning faulty firing with Ruthardt magneto, the regularity of the misfiring points to the defect being caused by a flat having formed on the fibre roller. The C.A.V. people will supply a new roller, as their sizes are the same.—I. COHEN.

Intermittent Misfire.

With reference to "F.W.R.'s" question in your issue of January 25th, I had the same trouble with a Ruthardt magneto. I found a small flat worn on the fibre roller, and at another time the spring blade was rubbing against the face of the contact breaker. I obtained another roller from Messrs. C.A.V., of Acton, and put a very small quantity of graphite on it to save the roller from sticking. I have not had a misfire since.—J.E.

Slip in an Enfield Gear.

I had the same trouble as "E.A.F.," and I wrote the Enfield Co. about it. They have always been very kind in replying to any query I have sent, but I still failed to get out the spindle of my two-speed gear. However, after thinking it over the method dawned on me early one morning in bed. I proceed as follows: (1.) Draw gear handle back into low gear position. (2.) Remove handle from gear rack and hexagon nut on end of thrust bracket. (3.) Take out four or six (six in older pattern, four now, I note) screws in thrust bracket and nut on thrust arm bracket. (4.) With spanner instead of gear lever on rack, turn the rack as far as it will go, *i.e.*, into lower gear position if that were possible. (5.) Insert piece of wood or spanner behind the thrust bracket. Pull rack up and turn it back so as to get a new grip of pinion on sliding cam. (6.) Turn spanner on rack and cam will come out. The whole secret is in putting a U-shaped piece over the sliding cam to take up the distance through which the rack turns.—W.G.H.



Method of withdrawing Enfield gear cam.

Starting a Single-geared Lightweight.

I notice your corespondent "W.B." states he has trouble starting his 2¾ h.p. two-stroke. I have a 2¼ h.p. Levis, and at one time had difficulty in starting on cold mornings. Now I take out the plug, a three-point Lodge porcelain insulated, fill it with petrol, by using the pet cock at the petrol lever, insert the plug again, and paddle off. I also flood the carburetter. I have never known this to fail, even when there has been a quantity of oil lying in the crank case, which splashes up into the top of the cylinder with the gas, and often fouls the plug if not primed. For easy detaching of the cable from the plug I have an open-ended brass connection. I do a good deal of riding in the dark, and a hint in your paper some time ago on how to fit a tell-tale bulb to a rear lamp has relieved me of great anxiety since I adopted it. The police are very keen on rear lights.—J. FAIRLAM HORN.

In your issue of the 25th ult., on page 84, there is a reply to "W.B.," who is experiencing trouble in starting his lightweight. I note that he has a Dixie magneto, and with this fitted the ordinary plug and platinum point gaps are quite useless. I venture to suggest that the cause of his difficult starting is that the gap at the plug points is much too wide. The Dixie magneto gives a diminutive spark, and the plug points should be set very close together, one-sixty-fourth of an inch being sufficient. With reference to the gap at the platinum points, .4 mm. is again much too wide; the makers themselves recommend a gap of from ten to twelve thousandths of an inch, but from my experience of a considerable number of these magnetos the platinum points must be set as close as possible. If "W.B." will set his plug points as close as possible, and the platinum points to the thickness of a piece of stiff brown paper, I think his starting troubles will cease.—W. STANLEY BANNER.

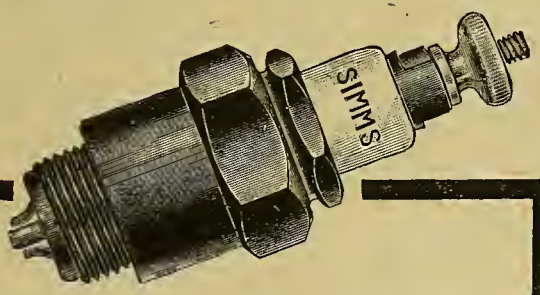
SIMMS NON-SOOT PLUG



With the Simms "Non-Soot" Plug, every care is taken to see that the gaps between the contacts are set correctly, and as a consequence, this plug does not short circuit, and can be relied upon to fire perfectly at all engine speeds. This plug, like the Simms Magneto, is of British manufacture throughout.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle" Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

We are living in

STRENUOUS TIMES . . .

All the more reason why one should not be saddled with a White Elephant in the shape of a motor cycle which is "NA-POO."

You have no time now to tinker about with a patched-up crock. When you buy a second-hand machine, it must be what it is represented to be.

In dealing with GODFREY'S you can accept their assurance that no machine is allowed to go out unless and until it is in every respect READY FOR THE ROAD.

GODFREY'S supply both New and Second-hand machines on Easy Terms of Payment, allowing full value for your old mount if taken in part exchange.

In fact, in any and every way GODFREY'S pride themselves on their service and attention to customers.

Write for our full lists of New & Second-hand Motor Cycles and Light Cars.

BIRMINGHAM Agent for Rovers, P. J. Evans, John Bright St.—1917 models in stock for immediate delivery.—See below.

1917 3½h.p. Rover Coachbuilt Combination, 3-speed countershaft gear, De Luxe sidecar; 90 gns.—Below.

1917 3½h.p. Rover, sporting model, racing or semi racing handle-bars; £57/10; extra for hand-controlled Pulipson pulley, £4/10.—P. J. Evans, John Bright St., Birmingham. [8191

1917 Rover Combinations, 1917 Rover 3-speed, countershaft.—W. Brandish, Charles Garage, Foleshill Rd., Coventry. [X5987

ROVER, 3½h.p., 1912, free engine, and coachbuilt sidecar, in real good order; £22, Percy and Co., 337, Euston Rd., London. [8181

ROVER Coachbuilt Combination, 3½h.p., 3 speeds, clutch, excellent condition; £48.—P. J. Evans, John Bright St., Birmingham. [8197

ROVER, new 1915, 3-speed, 3½h.p., absolutely equal to new, just overhauled, mileage under 3,000; £38.—Longman Bros., King St., Acton. [8146

ROVER Coachbuilt Combination, 1914-15, Sturmey 3-speed, lamps, horn, speedometer, beautiful condition, as new; £55.—Westley, Outfitter, Hales St., Coventry. [X9584

1912 3½h.p. Rover, Sturmey-Archer 3-speed, good tyres, with art cane sidecar, lamps, horn, speedometer, complete; £25.—Robinson's Garage, Green St., Cambridge. [8111

ROVER, 1913, 3½h.p., 3-speed, free engine, speedometer, lamps, horn, and accessories, Stelastic back tyre, in excellent condition; can be seen by appointment.—Bewsher, 173, St. James' Rd., Croydon. [8103

Royal Ruby.

ROYAL Ruby, 2¾h.p. J.A.P., 2-speed gear, late 1916 model, mileage 200, in perfect condition; £36.—Parker, Collin Croft, Kendal. [X5469

ROYAL Rubys actually in stock, £32, £40, and £46 each; exchanges entertained, deferred terms.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green. [8042

Rudge.

RUDGE, 1912-13, T.T., £20 cash.—William Marshall, Martin Dales, Lincoln. [X5778

3½h.p. Rudge Multi; £75; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0864

1912 3½h.p. Rudge, free engine, good condition; £25—R. E. Jones (Garages), Ltd., Swansea. [0785

RUDGE, 3½h.p., 1913 model; 20 gns.—Capt. E. Gait, Box L3,094, *c/o The Motor Cycle.* [8231

RIDER TROWARD'S, 78, High St., Hampstead.—1913 T.T. Rudge, special engine, very fast; 22 gns., bargain. [8247

1915 Isle of Man Rudge Multi, clutch, little used; owner in France; £45.—Particulars, Kendall, Ellesmere, Salop. [X5862

1913 3½h.p. Rudge, Multi gear, in perfect going order, and fast; £25, or near offer.—E. Bowden, Slinfold House, Bookham, Surrey. [8093

RUDGE, 1912, 3½h.p., 2-speed, coach sidecar, £29/10; 1913 3½h.p. Rudge Multi, new coachbuilt sidecar, £37/10.—Motor Exchange, Horton St., Halifax. [7794

1912 3½h.p. Rudge Multi, condition good, ready for road, all accessories; £25 to quick buyer.—Further particulars, Horne, Broughton Rd., Skipton, Yorks. (D) [8089

3½h.p. Rudge Motor, new 1916, with free engine, variable Rudge pulley, handles broke; £34; will buy T.T.—Write, Oakes, 4, Antrobus St., Winnick Rd., Warrington. [X5883

1913 3½h.p. Rudge Multi (1916 improvements), and coachbuilt sidecar, complete with screen, lamps, horn, and speedometer; £38.—Wilkin and Co., Hunter's Bar, Sheffield. [X5941

1915½ 3-speed 3½h.p. Rudge, foot and hand clutch, Lucas lamps, Stewart horn, 100 m.p.g., and sidecar; £48/10; after 6 p.m.—Dafern, 121a, Godolphin Rd., Shepherd's Bush. [X5980

RUDGE Multi, 1915, 5-6h.p., excellent condition, with light coachbuilt sidecar, speedometer, all lamps, etc.; £45.—Longman Bros., King St., Acton. 'Phone: 1578 Chiswick. [8145

1915 3½h.p. Rudge Multi, with sidecar, lamp, speedometer, in sound order; any trial; genuine bargain, must sell, going on service, £44 cash, or nearest.—Apply, John Cooke, Little Royd, Huddersfield. [8216

Scott.

COLMORE Depots, Birmingham, and Manchester, for Scott motor cycles. [0806

NEW MODELS FROM STOCK.

ALLON, 2-stroke, 2-speed	£42	0
B.S.A., 4¼ h.p., 3-speed, chain drive	£66	0
B.S.A., 4¼ h.p., 3-speed, model K	£64	0
BROUGH, 3½ h.p., T.T. model, 2-speed	60 gns.	
CALTHORPE, 2-stroke, 2-speed	33 gns.	
CALTHORPE-J.A.P., 2¾ h.p., 2-speed	28 gns.	
ENFIELD, 2-stroke, 2-speed	42 gns.	
ENFIELD, 3 h.p., twin, 2-speed	65 gns.	
ENFIELD, 6 h.p., Combination	90 gns.	
ENFIELD, 6 h.p.. Combination, with Lucas dynamo lighting set	105 gns.	
JAMES, 2-stroke, 2-speed	£42	0
JAMES, 3½ h.p., twin, 3-speed	£69	0
JAMES, 4¼ h.p., Combination	£86	0
LEVIS Popular, 2½ h.p., 2-stroke	£32	0
NEW IMPERIAL, 2½ h.p., 2-speed	39 gns.	
NEW IMPERIAL, 2½ h.p., 2-sp., clutch and kick-starter	46 gns.	
ZENITH-GRADUA, 3½ h.p., twin	£62	0

EXCHANGES.

We specialise in exchange transactions, and will allow full value for your old Motor Cycle or Light Car in Part Payment for any new one

SECOND-HANDS.

The following is a selection from our large stock of machines of all types:

CLYNO, 1914, 6 h.p. Combination, Lucas electric lighting set, speedometer	£68	0
JAMES, 1915, 2¼ h.p., 2-stroke, 2-speed, Lucas lamp set, rear lamp and horn	£33	0
ALLON, 1915, 2¾ h.p., 2-stroke, 2-speed	£33	0
MATCHLESS, 1913, 8 h.p., 2-speed, clutch, & kick-starter, all accessories	£38	0
ZENITH, 1913, 3½ h.p., Gradua gear	£30	0
CALTHORPE, 1915, 2¼ h.p., 2-stroke, 2-speed, headlight, rear lamp, horn, and speedometer	£28	0
VINDEC, 1911, 5 h.p., 2-speed, headlight, rear lamp, horn and coachbuilt Sidecar	£22	0
DOUGLAS 1915 2¾ h.p. War Office model	£50	0
TRIUMPH, 1914, 4 h.p., 3-speed	£40	0
JAMES, 1916, 2¼ h.p., 2-stroke, 2-speed, lamps, and horn	£36	0
ROYAL ENFIELD, 1914, 3 h.p., twin, 2-speed	£32	0
DOUGLAS, 1910, 2¾ h.p., lamps and horn	£15	0
CALTHORPE-MINOR, 1914, 2 h.p., 2-sp., and free engine	£15	0
CALTHORPE-J.A.P., 1915, 2¾ h.p., 2-sp., lamps and horn	£30	0
NEW IMPERIAL-J.A.P., 2¼ h.p., T.T. model, 2-speed, Cowey speedometer	£33	0
ALLON, 1916, 2¾ h.p., 2-stroke, 2-speed, Lucas lamps, and horn	£38	0
ARNO, 1916, 3½ h.p., T.T. model, lamps, and horn	£33	0
ALLON, 1915, 2¾ h.p., 2-stroke	£25	0
CALTHORPE-J.A.P., 1915, 2¾ h.p., 2-sp.	£27	0
TRIUMPH, 1912, 3½ h.p., Bowden countershaft 2-sp. gear, clutch, and kick/starter	£28	0

Deferred Payments accepted for either New or Second-hand Goods.

MOTOR CYCLES FOR SALE.

Scott.

SCOTT, 1913, and sporting coachbuilt sidecar, in real good order and condition; £32.—Percy and Co., 337, Euston Rd., London. [8172

SCOTT, 1914, overhauled, fitted with pan seat, spare tank; £32; extended payments arranged.—Service Co., 292, High Holborn, London. [X5910

Singer.

SINGER, 1913, 3½h.p., 3 speeds, coachbuilt sidecar; £33/10.—Motor Exchange, Horton St., Halifax. [7797

SINGER, 2h.p., Bosch, B. and B., Druids, M.A.C., overhauled, excellent condition; £15.—Head, 31, Hainthorpe Rd., West Norwood. [8133

SINGER, 3½h.p., 1914, Bosch, B. and B., decompressors, splendid tyres; any trial or examination by appointment; £15.—Price, 141, Butt Rd., Colchester. [8025

Sun.

COLMORE Depots, Birmingham and Manchester, for delivery from stock of all models of Sun motor cycles. [0807

1916 Sun-Jap, 6h.p., 3-speed, kick start, Watford trip speedometer, Klaxon, with Millford sidecar, perfect; any trial; £80.—A. Horne, 77, High St., Aldershot. [X5658

1914 2½h.p. Single-cyl. Sun-Precision, Clincher Dreadnought tyres, Bosch mag., free engine clutch, in very good order.—The Premier Motor Co., Aston Rd., Birmingham. [8204

Sunbeam.

6h.p. 1915 Sunbeam Combination, new Palmer cords, 3in., lamps, Low generator; £90.—Brown, Belle Vue, Thetford. [X5867

SUNBEAM, 2¾h.p., new tyres, lamps, mechanical horn, mudshields; £32, or near offer.—Manager, 113, Bridge St., Warrington. [X5175

1915 3½h.p. 3-speed Sunbeam Combination, fully equipped, excellent condition; £80; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0862

SUNBEAM, 1916, 3½h.p., speedometer, lamps, horn, just overhauled by makers, perfect; £75.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [8075

SUNBEAM, 1915, 6h.p., with best Sunbeam sidecar, overhauled and guaranteed; £85; extended payments arranged.—Service Co., 292, High Holborn, London. [X5911

1915 3½h.p. Sunbeam, 3-speed, countershaft, hand-controlled clutch, very good condition, 2 lamps, horn, usual tools; £60.—Robinson's Garage, Green St., Cambridge. [8110

3½h.p. Sunbeam, 1915 model, very little used, fitted with handsome coachbuilt sidecar, complete with Lucas lamps, and speedometer; £85; condition like new, guaranteed.—Wauchope's, 9, Shoe Lane, London. [8125

SUNBEAM 1914 6h.p. Combination, splendid condition, Lucas lighting set and horn, speedometer, leg shields, pillion seat, Gloria sidecar, wind screen, detachable child's seat, coachbuilt luggage box to fit chassis, spare tube, first-class order; 75 gns.—Axten, Glengarriff, Surrey Rd., Harrow-on-Hill, Middlesex. [8218

SUNBEAM Late 1915 6h.p. Combination, Lucas dynamo lighting set, electric horn, speedometer, mirror, pillion seat, detachable interchangeable wheels, spare wheel, new tyres, sidcar hood and screen, folding luggage carrier, magnificent outfit, little used; price £140.—A. B. Staples, 33, Old Change, London, E.C. 'Phone: City 186. [8219

T.D.C.

DE LUXE T.D.C., 1915, 2¾h.p., 2-stroke; first offer £17; nice mount.—Smiths, Motors, Girvan. [8083

Triumph.

IF You Want a Triumph, try the Walbro Garage, below

1913 3½h.p., 3-speed, large lamp and horn, with coachbuilt sidecar, just being repainted, bike in excellent condition, new sidecar tyre, others very good; £38.—Below.

1912 3½h.p., free engine, all in good order, lamps, horn, and tools; bargain at £21.—Below.

1914 4¼h.p., 3-speed, P. and H. lamps, speedometer, horn, and cane sidecar; £40.—Below.

THE Walbro Garage, Ely, Cambs. 'Phone: 48. [X5860

1914 4h.p. Triumph and Sidecar, as new; £38, or offer.—46, Alfred St., Islington, N. [8084

TRIUMPH, 1914 4h.p., very little used, all fittings, new back tyre; £47.—Gray, Hallgate, Doncaster. [X5805

1911 Triumph, free engine model, T.T. bars, all necessories; £19.—Harvey Hudson, South Woodford. [0892

1910 Triumph T.T. Roadster, N.S.U. gear, new belt, tyres good; £20.—Harvey Hudson, South Woodford. [0893

3½h.p. 3-speed Triumph, late 1913, Gloria sidecar; bargain, £40.—East, 6, Wintringham Rd., Grimsby. [X5646

1909 3½h.p. Triumph, good engine, tyres and belt, lamps and horn; £17.—Blake, 69, Ferntower Rd., Canonbury. [8085

The Petrol Position—Suggested Refund of Licence Fees.

THE bombshell dropped by the Petrol Committee last week was not entirely unexpected in some quarters. We do not quarrel with the Government's decision if the conditions demand such a drastic step, but we do strongly protest against the Order being issued immediately after January, during which month licences had to be paid on motor vehicles. The Post Office accepted the amount without demur, yet the licences distinctly state that they continue in force until the 31st of December.

It has been suggested by many of our readers that the Government officials have set a trap to get their licence fees first and then to announce that no more petrol will be forthcoming after March. There certainly is a *prima facie* case to this effect, but we incline to the view that it is a case of bad bungling due to lack of proper co-ordination between the departments concerned. Nevertheless the result is the same. Do the authorities imagine that motor cyclists are willing to pay a full year's licence for a quarter of a year's riding?

The Government cannot in justice retain in full the fees which have been paid this year, yet it will mean a great deal of trouble and delay, and much clerical work in Government Departments which a little imagination on the part of those in authority could have avoided. We feel that it is the duty of the different organisations which exist for the protection of motorists' interests to get to work immediately. If no petrol or petrol substitutes are available after March then threequarters of the tax paid should be refunded. It is a perfectly reasonable and legitimate request, for pleasure motoring nowadays is unknown, though we have always contended that a little recreative motoring is beneficial to body and mind, and quite as justifiable as railway trips to the seaside or other health resorts. Business men find that they cannot get on without a motor vehicle of some sort, and naturally in these economical days they turn to the cheapest forms of motor vehicles, particularly the motor cycle, which is cheaper than travelling by train. Will the Petrol Committee admit that men who apply their machines to business uses are doing so in the national interest? What of the case of men who live in the country; will they be made to adopt the Government's idea of economy and lose time by walking far and then journey by train?

The Utility Side.

Of course, motoring will not cease entirely. The motor vehicle has demonstrated too thoroughly its utility and importance for it to be dispensed with altogether. It is part of our everyday life. Motor cycles are largely used by men engaged upon work of national importance about which there can be no dispute. We have in mind doctors, veterinary surgeons, farmers, gardeners who have to inspect widely-separated tracts of grounds, builders engaged upon urgent Government buildings in outlying districts, Government examiners and inspectors. Again, supplies should be forthcoming for the National Motor Volunteers, the special constabulary, and people connected with the British Red Cross and V.A.D. services, also trade firms engaged in the development of designs. Thus it will be seen that the motor cycle permeates the most important channels of utility, so to suggest that motor cycling is to cease is a gross exaggeration of the position. As we have said, what we object to, and that most emphatically, is the suspicious delay, until the licences were paid, of an announcement which must have been settled weeks ago. Our readers use very strong terms at the injustice done to them, and the mention of the fact will serve to show the Government that their action is very strongly resented, and is not likely to produce that popularity and support which we could all hope to see exist.

An index to the advertisements in this issue will be found on the page facing the back cover.

MACHINING A CYLINDER.

How this Difficult Operation may be Performed at Home with Suitable Tools.

AT the present time, when such great difficulty is experienced in obtaining new parts for a motor cycle, to say nothing of the cost of them, the following description of how I machined up a cylinder for a Triumph motor cycle engine may be of interest to other riders, more especially to the fortunate possessors of the necessary tools for carrying out the work.

Having frequently noticed cylinder castings advertised in the columns of *The Motor Cycle*, and finding them of suitable dimensions for my requirements, I secured one.

The first operation consisted of plugging the small hole in the compression tap boss at the top of the casting and then finding the centre of the cylinder by reference to the outside curve of the radiating fins. A ⅛in. hole was then drilled at this point to accommodate the back centre of the lathe during the process of turning the spigot of the cylinder and facing both sides of the square flange, for which operation the casting was mounted on a four-jaw chuck. Four holes were next drilled in the square flange for the holding-down studs, the holes being marked off by means of a sheet iron template.

Boring the Cylinder.

For the purpose of setting up the cylinder for boring, a circular piece of boiler plate ½in. thickness and about 12in. diameter was obtained. This plate was bolted to the face-plate of the lathe by means of three 1in. studs, or distance pieces, of sufficient length to admit the cylinder casting being placed between the two. A hole was then bored in the boiler plate to fit the spigot end of the cylinder, and the latter was then bolted in position. The arrangement is clearly shown in the photograph (fig. 1). A boring tool of the ordinary type was used, made as stout as the tool holder would accommodate—that is, 1in. square steel. It was necessary to take light cuts for the sake of ease in driving the lathe by foot power, also to avoid springing and chattering of the tool. After boring, the cylinder was lapped out by means of a wooden lap, somewhat smaller than the bore and covered with emery cloth well lubricated with oil.

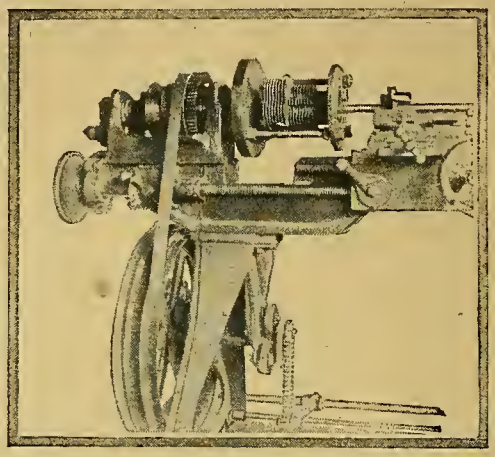

Fig. 1.—Method of fixing the ½in. boiler plate to the face plate of the lathe.

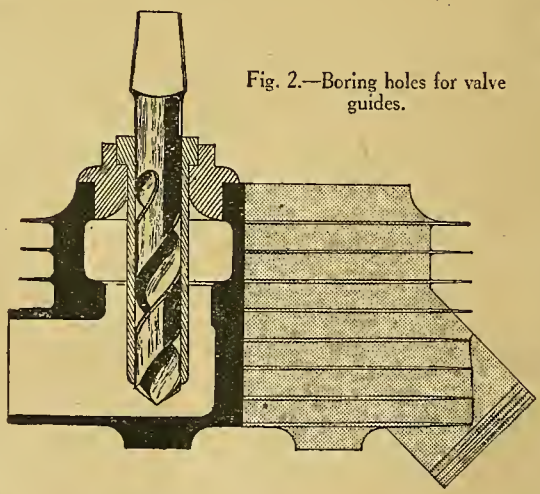

Fig. 2.—Boring holes for valve guides.

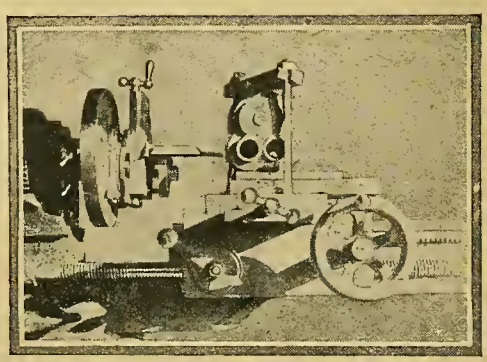

Fig. 3.—Machining the inlet and exhaust connections.

Machining the Valve Seatings.

Next the valve chambers were marked out to coincide with the measurements of the old cylinder; a circle was scribed on each valve chamber face to facilitate setting up on the face-plate, which was accomplished by bolting the previously-mentioned boiler plate, together with the cylinder, directly to the face-plate in the reverse position to that adopted for boring. Having machined the valve seats and screwed the chambers to receive the valve caps, it was necessary to make a guide for the twist drill used in boring the bottoms of the valve chambers to receive the guides. This was done by screwing a guide into the inlet valve cap in the position of the sparking plug. Fig. 2 shows the arrangement with the twist drill in position for boring.

For the turning, boring, and screwing of the carburetter and exhaust pipe connections, the slide rest was removed and the cylinder bolted down on the saddle of the lathe, the slide rest being mounted on the face-plate of the lathe, and the shanks of the tools were bent at right angles to enable the work to be done. Fig. 3 clearly shows the arrangement, and it made quite a first-class job.

The cylinder bore was intentionally left a shade under size, and a very light cut was taken off the piston to true it up to fit the cylinder. The skirt of the piston was reduced to clear the cylinder walls to eliminate friction. Since carrying out the above repair I have ridden over a hundred miles with the new cylinder, and find it a great improvement on my old one, which had a cracked valve seat.

The whole of the work was carried out on a 5½in. centre screwcutting treadle lathe at a cost of under 10s.

W. P. WALKER, A.M.I.Mech.E.

Occasional Comments by "Ixion"

Front Brake Details.

ANYBODY who has acted as a judge in the "condition" examination at the finish of a reliability trial knows that the loss of front brake shoes is one of the commonest grounds for a penalty; and anybody who has ridden as many makes of motor cycle as I have knows that the front brake is the most inveterate source of annoying rattles. They commonly arise at two points. The first is at the bearings in which the tips of the steel horseshoe ride, these bearings being fixed to the forks. The second is between the down rod to the horseshoe and the steering head; a swivel is usually inserted in this rod to cope with any change of alignment as the shoes bed into the rim, and on many machines the only precaution taken to prevent the rod rattling against the steering head is a clearance; the rod is set out, say, half an inch from the head, and the maker is sanguine enough to suppose that it will not sway enough to foul the tube. As its only bearing is usually close to the handle-bar, it usually sways more than half an inch at the bottom, and you have to wrap insulating tape round the lower part of the head to stop the noise. I have just been trying two 1917 machines of good make, and both of them suffered from these two irritating defects. Other makers have eliminated them, and they should both be conspicuous by their absence from all 1917 designs.

More Conversions to the All-chain Drive.

IT is now notorious that the end of the war will reveal many more conversions to the all-chain drive, including some notable firms. The meaning of the change can perhaps be understood if I mention that the Douglas remains recalcitrant, and retains its well-tried chain-cum-belt transmission. In the 2¾ h.p. Douglas we have a machine of which low weight has always been a special attraction, and which is not intended for sidecar work, though some enthusiasts do not hesitate to burden it with the double load. The Douglas retention of the belt as an item in the drive possibly may be interpreted as follows: "The belt is perfectly satisfactory for solo work; if we adopted the all-chain drive, we should have to strengthen the frame, and to incorporate one or two anti-shock devices, which would add totally unnecessary weight." I will not be so foolish as to regret the disappearance of the belt from one or two of my old favourites until I have tried their all-chain models. But, personally, I had no quarrel with the drive which these firms are scrapping; if I had been a sidecar enthusiast, I might have viewed the change more complacently. As it is, I must submit with my best grace to seeing the chain adjustments complicated, and the weight slightly increased, for the sake of those numerous riders who indulge in sidecar work with a 500 c.c. engine. And I ought to admit that the chain-cum-belt drive is just perceptibly snatchy on single-cylinders at slow speeds, whereas a properly cushioned chain drive is absolutely shockless on a good twin. No doubt it will be equally smooth on the new singles, though my experience of all-chain singles in the past has hardly suggested such possibilities.

"Some" Bicycle.

HOW many readers noticed "Excelsior's" assertion in our issue of February 1st to the effect that his Villiers two-stroke could "easily climb" Sunrising on a gear of 5¼ to 1? I have not owned a Villiers engine; but I have never owned a baby two-stroke which would look at a hill of that calibre on its top gear. As the correspondent mentions several other fairly steep hills in the same connection, I presume there is no slip of the pen. Do other readers make similar claims? I have just discovered a new merit in the babies. There has now been practically continuous frost since December 1st, and when the weather was mild for a day or two I had no leisure to tackle the decarbonisation and tuning jobs for which each member of my stud was sighing. As my garage is unheated, I have waited two months for a day on which spanners would not give me frost-bite, and the other day I caused a great fire to be lighted in the drawing-room, laid brown paper all over the carpet, stalked into the garage, tucked my baby two-stroke under my arm, carried it into the drawing-room, and decarbonised it there very comfortably without exciting Mrs. "Ixion" to do more than threaten an offensive.

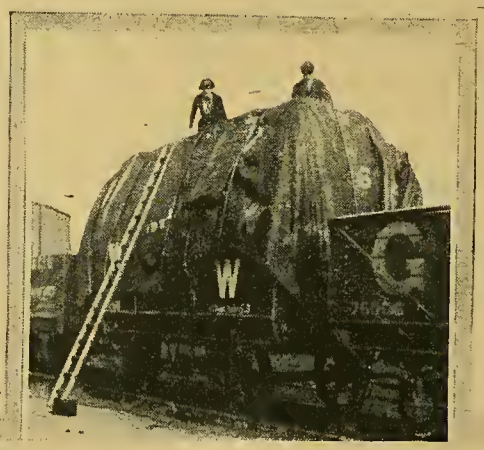
Springs and Mudguards.

I CONFESS to being a little surprised that the Government has not placed larger orders for spring frame machines. In my experience they vastly reduce the frequency of petty troubles and permit of hard riding with a minimum of fatigue, two benefits which ought to outweigh any conceivable objections. However, nothing short of complete inside information on the expense and dislocation of the factories involved could justify dogmatism on this point. As to mudguards, wherever there is thick traffic travelling over liquid slime you have to clean your attire daily, not because your own mount is a mud flinger, but because other traffic flips it sideways all over you. For these reasons the perfectly mud-guarded machine is something of a delusion, except for dwellers in the country. I personally choose the line of least resistance in these matters; I don an oilskin or other waterproof suit, and turn the hose on it at the journey's end. If I rode exclusively in the country or in small towns, I might set a higher value on idealism in mudguards; as it is, I frankly prefer more sightly fittings and more get-at-able tyres. It is further true that the latest machines, with compromise mudguards and a pair of footboards (instead of rests), bring one home moderately clean. After twenty miles over rural roads on one of them one is not dirtier than if one had ridden a similar distance over London's suburban arteries.

War Work and Lady Motor Cyclists

Further examples of the usefulness of the Motor Cycle in Womens – National Services.

THE war has developed latent qualities among the women of England, no matter what their station in life may be. From the highest to the lowest all are "doing their bit" with an amazing cheerfulness and with an ability and energy which surprises those who had regarded the women of this country as frivolous and pleasure loving. In the hospitals, in the factories, on the farms and market gardens, women are now to be seen doing work which in previous days was regarded as essentially men's portion, and doing it cheerfully and well. The prejudice against female labour is gradually being overcome, and those who have employed women are loud in their praise of the capacity they show, and the tireless devotion to duty which they exhibit. The means of reaching their centres of work present many difficulties to some, particularly those who live in the country. The train and tram services usually suffice for town hands, but those working in the country, where housing accommodation is so limited, find a bicycle almost indispensable. Happier still are those who possess motor cycles, for they can undertake duties releasing men for the Army which those less fortunately situated cannot accept.



(Top) Superintending the sheeting of a load of hay
(Bottom) Transports passing through Cirencester

Women's Adaptability.

Two Gloucestershire ladies, who previous to the war lived in happy surroundings at home with no business cares to worry them, have undertaken work which a few years ago would have been regarded as absolutely outside the scope of woman. They are Miss Maude Stephens and Miss M. C. Parker, both motor cyclists, and both are now holding responsible positions as Government forwarding supervisors of forage supplies.

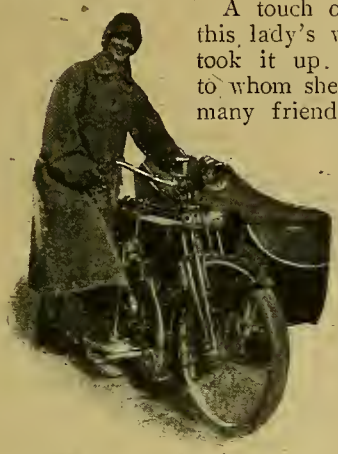
Miss Stephens's duties are varied and onerous, but she thoroughly delights in them. Those who have no knowledge of the work of this department would be astonished at the amount of forage which has to be supplied to the troops. Motor lorries and horse waggons are continually plying between the various farms and railway stations, and the supervisor has to see that all works smoothly, and that the requisite amount of hay and straw is consigned to the proper destination. Visits to the baler, which is constantly being moved from farm to farm, have to be made regularly, and from the farms journeys have to be taken to the various stations in the vicinity to check and weigh the bales. This accomplished, the superintendent returns to the office and supplies the consignee with full particulars as to weight, numbers, etc., and the name of the farmer from whom the consignment comes.

From this description it will be seen that Miss Stephens's days are fully occupied, and without a motor bicycle she would find it absolutely impossible to get through the work. Miss Stephens rides a 2¾ h.p. Douglas week in and week out, in all weathers, and usually she returns to her rooms at night healthily tired, but with the satisfying feeling that another good day's work has been accomplished in her country's cause.

So far, Miss Stephens has had no difficulty in getting sufficient

War Work and Lady Motor Cyclists.—

petrol, and has not had to make use of any substitutes.



Miss M C. Parker in her winter rigout.

A touch of romance is added to this lady's war work, for since she took it up she has met an officer to whom she is now affianced. Her many friends wish her the best of luck, and their kind thoughts will follow her to her new home in South Africa after the war.

Miss Parker has control of the Stonehouse district, and her work is in every respect similar to that of Miss Stephens. In addition, however, Miss Parker has two Government stores, one holding 500 tons of hay, and the other 400, to look after. At present she has two motor transports with four men on each, and sixteen soldiers in the stores under her control. To accomplish her work she rides a 3½ h.p. standard Sunbeam, of which she speaks most highly. Being a capable mechanic, she is able to repair ordinary mishaps herself, but during the dark days of last autumn she experienced an alarming side-slip, which, fortunately, did not result in anything serious. On the "safety first" principle, however, she now runs with a sidecar when the roads are greasy or snowy, for, no matter what the weather, the work has to be done.

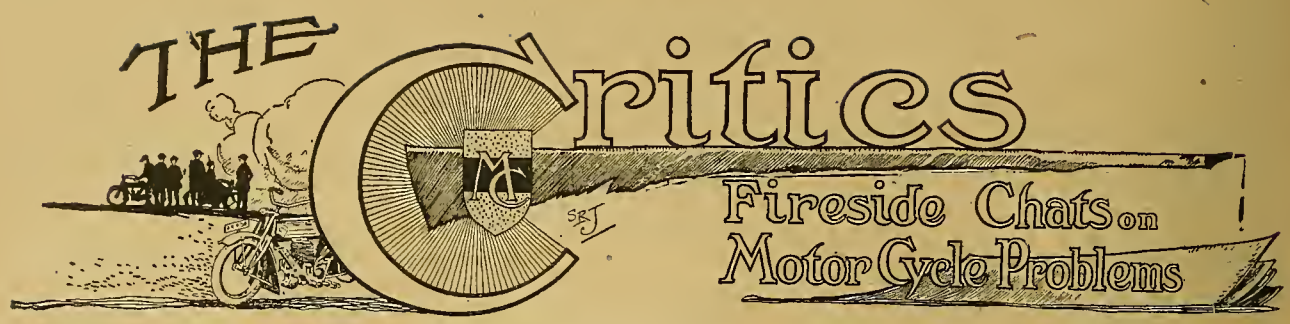
Miss Maud Stephens on her Douglas.

Here we have two instances of how the girls of England are doing their bit, and both Miss Stephens and Miss Parker are thoroughly enjoying the experience. The fact that they are doing really valuable work is sufficient compensation for them both, but, in addition, the life is a healthy one, and the continual motoring about the country in the fresh air has given them that ruddy appearance which only accompanies perfect health.

M. HARTLEY-SMITH.

A SCOTTISH PANORAMA.

An advantage the road user has over the traveller by trains is the enjoyment of magnificent panoramas. In these days of speed gears and efficient engines the steepest hill does not alarm the motor cyclist—indeed, hills only add to the zest of a run. The above picture is of the Clyde from Kirkfieldbank Hill. Those who know the Yorkshire coast may be struck by the similarity, on first glance, of the view of Whitby from the heights inland.



"YOU say a modern motor cycle is perfect? For the life of me I cannot understand why British manufacturers have refused so long to fit mechanical oil pumps." The observation was by a Journalist, with a complacency of criticism inspired by the possession of the only comfortable chair in his room. "As for mechanical pumps," the Novice remarked, "I don't even know where they put the things! It takes me all my time to keep my old jigger running as it is, and I couldn't adjust a pump even if I had one. What's the matter with a pumpful every ten miles? It's easy to remember."

Little Adjustment Required.

"If there is one thing that needs to be left severely alone," retorted the Journalist, "it is a mechanical oiling device. But there is no reason why it should give you any more trouble than a drip feed—the other way round, in fact! Its working doesn't depend on your memory, and all you have to do is to give the feed valve one-half or one-quarter turn, according to the temperature, when you set out. The thing looks after itself."

"Do you speak from a journalistic point of view, or from practical experience?" demanded the Manufacturer with an air of truculent defence.

"From experience. The fact that my last three machines were all fitted with mechanical feed is sufficient proof. Indeed, that point influenced my choice more than anything else."

"And haven't you experienced any trouble?" asked the Novice, regarding the Journalist with the wondering admiration Henry VIII. might have bestowed upon a monogamist and teetotaler.

"Absolutely none! On cold mornings you have to turn on a little more oil, but that is a simple matter. The common notion that a mechanical pump means extra care is absurd."

"I have heard it said," put in the D.R. impressively, "that no mechanical device can govern a steam engine like a human governor. I rather fancy the same applies in governing the supply of oil to a petrol engine."

But the Journalist was obdurate. "An engine driver is a trained man," he pointed out. "Motor cycle manufacturers cannot cater for trained men. They have to think of the juggins." All three looked rudely at the Novice, who busily brushed his waistcoat—a nervous habit he had acquired owing to its protruding expanse being particularly prone to collect tobacco ash. "He has to strike a delicate compromise between mechanical perfection and bedrock simplicity," added the Journalist.

The Opposite Opinion.

"Which is exactly why he hesitates in adopting mechanical oil feed," stated the Manufacturer. "You talk about adjusting the supply to suit the temperature, but that is not the only point to be considered. The natural density of the oil used is equally important. In your case the system happens to prove good, because you keep your drum of oil at home, and fill up every time with the same brand. Other men—particularly the novice—fill up anywhere, at any time, and with any grade of oil that happens to come handy. Just imagine the absolute beginner re-adjusting his pump to suit all these various conditions when the slightest misjudgment may mean a dry engine."

"You cannot depend on the absolute beginner to do anything, except to let the clutch in—with a bang," the Journalist pronounced. "The advantages of the mechanical pump feed system are obvious to the rider of normal intellect. In the first place, it feeds the oil in a proper flow to the points where it is most needed, instead of leaving the flywheels to slop it about haphazard."

WHAT IS IT?

At first glance one might well ask. The picture shows the curious effect produced by an amateur photographer who attempted to snap a motor cyclist in mid air.

"True," agreed the Manufacturer. "Still the problem is a knotty one. First, there is the question of price; then, do you know that a certain manufacturer nearly lost his reputation by fitting a pump to feed oil slowly to the engine—so slowly, indeed, that it nearly stopped, and the big end bearings gave out?"

"That is no argument," the Journalist retorted. "There was once a flying man who lost his life trying to fly, but the machine he invented is to-day one of the best above ground! Because one pioneer made a mess of it, are the rest going to fight shy instead of wading in? My Aunt Matilda got stung by a jelly fish when wading up to her ankles to avoid jelly fishes. If she had waded in up to her knees like the Americans on the same shore, she probably would not have been stung at all!"

The Novice suggested that that was one in the eye for the Manufacturer, and that jelly fishes constituted a dainty only the rich could indulge in. Then the D.R. relieved the tension of the moment by stating his views, which usually came from any point of the compass that happened to suit him.

Invisible or Visible Feed.

"I think," said the D.R., "that the defect in present mechanical systems is that the feed is not visible to the rider. That, really, is the fly in the ointment. The man on the machine should be able to see the feed and to adjust it from his seat."

At this point the Novice had something to say about waterproof covers for seats, but the ex-soldier waved him silent.

"This, of course, means complications in the way of pipes," the D.R. proceeded, "and the further the oil has to flow the more its density will govern the speed at which it flows. Still, I think the sight feed is worth a lot, as if one cannot see the flow of oil one always suspects the pump of malingering when the engine refuses to pull."

"There may be something in *that*," the Manufacturer agreed. "If the adjustment were on the tank and the flow visible one could then govern the supply to meet the extra demand of a head wind or a very long gradient. Fancy having to get off and turn off the oil when descending a mountain, as one has to in present day systems! The supply of oil to the engine *must* be governed by haud, no matter how it is fed."

"If you read the motoring journals," stated the Journalist, "you would know that the latest productions *are* governed by hand, and yet are entirely mechanical. The supply is determined by the throttle,

The Critics.—

opening, which is undoubtedly the right system."

The Manufacturer grinned. "Very nice on paper," he mumbled, "which is the chief point with you journalists. But we manufacturers have to consider absolute reliability when the good name of our engines depends upon it."

What Constitutes Reliability?

"In my opinion," replied the Journalist, "if you can lend your machine to a friend, and know that it will be properly lubricated, whether he rides it five or seventy miles, that is the true test of reliability."

"What could be simpler than telling your friend to push the plunger down every five or six miles?" demanded the Manufacturer. "That is all you have to do with the ordinary hand feed."

"Nothing could be simpler," replied the Journalist, "except having to tell him nothing at all—as in the case of the mechanical pump."

The D.R. and the Novice chuckled audibly. From the security of the couch shadows the Journalist's dog growled at the Manufacturer, and, all things considered, popular feeling was against him.

The D.R. prepared to deliver the *coup de grâce*.

"The ordinary rider can't judge five or six miles," the Discharged Soldier pointed out, characteristically plastic in his views. "He pushes down the plunger every two or every sixteen miles, as he happens to think of it. He does not even make sure that the pump draws its full charge, nor does he realise, in changing machines, that no two pumps draw a like amount. The overall result is that his engine is either over-alled or under-alled!"

"You mean," suggested the Journalist, "that either he under-oils, or his over-alls are all over oil through over-oiling?"

"That's it," the D.R. agreed. "Generally he over-oils to be on the safe side, and since the manufactnrer does not have to pay his oil bill or decarbonise his engine, he rather likes it. He prefers it to the risk of under-oiling by mechanical pump. He can hold the owner responsible for under-oiling and worn bearings so long as the feed is hand governed, but immediately we have mechanical pumps, which the manufacturer himself designs and sets, worn bearings will be at his own door-step."

"I consider it is easier perpetually to over-oil with a pump than with the alleged hit and miss principle," stated the Manufacturer. "And why, in big races, are the machines equipped with mechanical pumps invariably equipped with a hand pump in addition? It looks rather as though they were not very confident in their system, doesn't it?"

The Journalist shrugged his shoulders.

"As regards the argument," the Novice added, "it seems to me that any sort of lubrication is good so long as delivered in judicious doses."

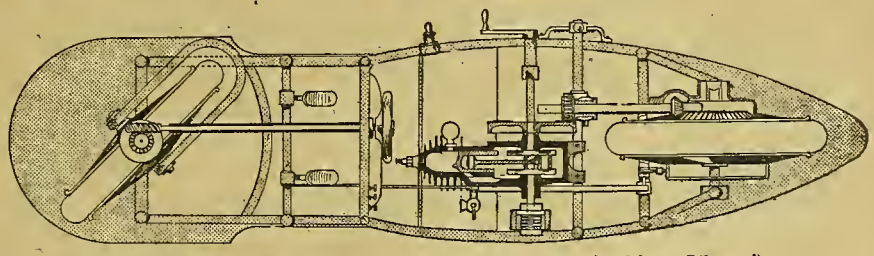
At this juncture the Journalist's landlady retired noisily to bed, asking her tenant if he would kindly put the hall light out. Ere the night was through, in that automatic way that arguments have of switching round, the Manufacturer was talking in favour of mechanical feeds from the private owner's point of view, while the Journalist was arguing hand pumps from the Manufacturer's standpoint—which seemed to indicate that both were open to conviction—till, on the door-step, the D.R., with kindly enquiries after Aunt Matilda, was the last to depart.

Then the Journalist put out the dog, and left the hall light burning, and, trudging to bed, he felt some of the joy of a great and single-handed achievement.

A CAR TYPE SOLO MOUNT.

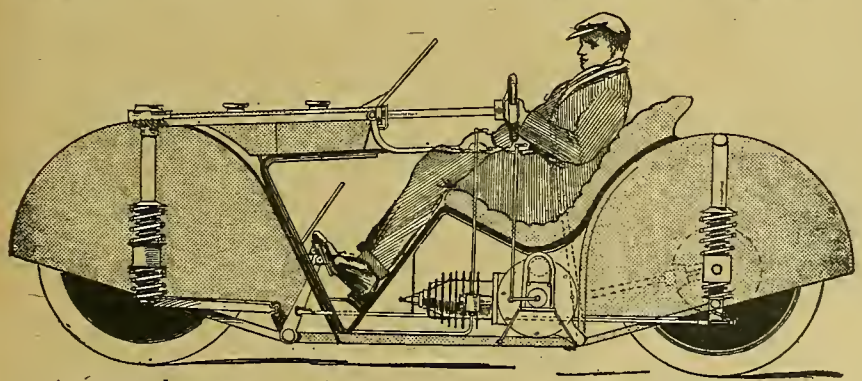
An Original Attempt to Evolve a Weatherproof Motor Cycle.

MANY efforts have been made to evolve a truly wind and weatherproof motor cycle, but so far the solo mount on car lines, having the luxuries of a cushion seat, wheel steering, and windscreen, has failed to win the appreciation of the somewhat sceptical solo rider. From time to time we have regaled our readers with the efforts of amateur genius in productions of this kind, and the accompanying illustrations convey some idea as to what might be accomplished. True car comforts would be appreciated by many a solo rider, but, unfortunately, there are other things just as dear to him. He is troubled, for instance, by a subtle forehoding that some day, sooner or later, he is sure to come off, and he is obsessed by the desire to do it in the open air, rather than in the restricted space of a weatherproof body.



The designer gives this vehicle the quaint appellation of "Motor Bikecar."

In spite of the sense of profound luxury which the accompanying illustrations convey, the machine would appear to possess one or two minor defects which have evidently escaped the eye of its inventor. Front wheel side-slips may confidently be expected, the arrangement of the front wheel steering being on car lines instead of on motor cycle lines.



A car type solo mount—a reader's serious attempt to solve the problem of weatherproofing the motor cycle.

The Fly-open Door.

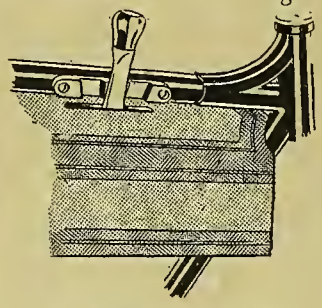
We are informed that "fly-open" spring doors are to be fitted at either side, so that on bringing the machine to a standstill the driver can thrust out one leg, and thus support himself and the machine. We shudder to think what would happen if he thrust out the wrong leg, or the door refused to open at the critical moment!

The framework being 50% heavier than a standard frame, the inventor proposes reducing the weight of the power unit in order to compensate for this—an ingenious solution which, we fear, would not meet with the approval of the speed merchant. But then, of course, the inventor is not out to catch the eye of the speed man, and those to whom this type of machine would appeal most strongly are willing to sacrifice a good deal for comfort and shelter. In this case we have, as further compensations, the luxury of a friction gear, giving an infinite range of speeds forward and reverse, a shaft drive, telescopic wheel steering, and a special shape of combustion head, which in itself is as original and curious as is the whole design of the machine.

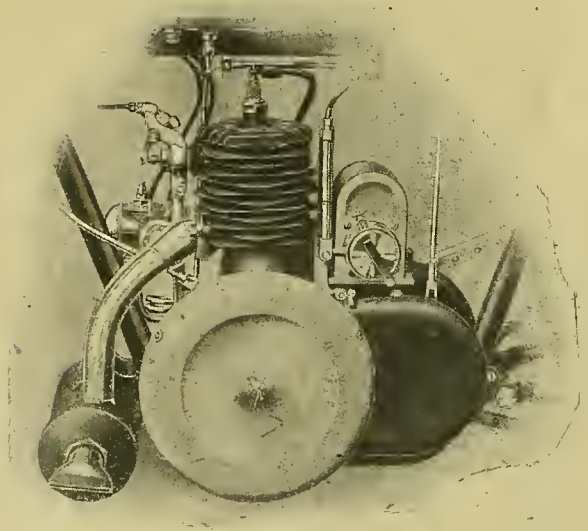
TWO WINTERS ON A JAMES TWO-STROKE.

The Advantages and Limitations of a Baby Lightweight.

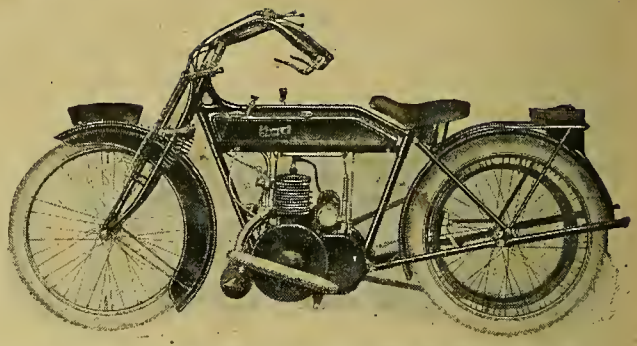
THE baby two-stroke is in some senses a tantalising machine. It is infinitely lighter than most motor cycles, and therefore specially adapted for odds and ends of trips. Few people regard it as the ideal mount for long non-stop runs, but it is deliciously convenient for all short spins, and especially so for a round of calls necessitating frequent stops. Nothing compares with it for such purposes except the baby four-stroke; and the baby four-stroke is far more vibratory, and has a less pleasing exhaust, besides being more difficult to re-tune after a spell of hard work. Furthermore, the baby four-stroke is very apt to "dry up," or otherwise complain if driven hard, whereas a well-run-in two-stroke revels in full throttle work, provided one can get a sparking plug which will stand the racket. On the other hand, a baby two-stroke needs very precise handling, and therefore does not give of its best until you have mastered your sample, and learnt its special whims; if, for example, you are reckless and haphazard in your oiling methods, you will get a lot of four-stroking, you will soot the plug with annoying frequency, you will carbonise the top ring hard into its groove in a very few miles, and you will have to spend the usual forty-five minutes in decarbonising it much too often. Finally, baby two-strokes vary exceedingly in quality. For all these reasons one hears varied reports of these wee machines.



The gear control lever passes through the tank.



The power unit of the James two-stroke. The engine has a capacity of 64 × 70, equalling 226 c.c. Observe the staggered ribs, a distinguishing feature of the James engine.



The 2¼ h.p. James has a two-speed countershaft gear, the primary drive being by an enclosed chain on either side of the crank case and thence by belt.

But the simple truth is that if a good machine is bought and intelligently handled it cannot be beaten for runabout purposes, whether as the only mount in the stable or as a tender to a bigger machine reserved for long distance work. To my mind, its suitability for long distance work is confined to very cold weather, in which pace is uncomfortable, or to elderly and timid riders who are contented with comparatively low speeds.

A Satisfactory Mount.

For the past two winters I have owned a 2¼ h.p. James two-stroke, which has done really hard work over very bad roads with real faithfulness. It was driven very gingerly for 500 miles, until the engine had settled down, and ever since it has been rattled about without sparing, and has not resented the treatment. It is substantially constructed, and none of its details ever gave me any trouble, apart from the occasional loss of a nut or a screw, when I was careless in going over the twiddly bits after fast work on bad roads; one is apt to neglect a general purpose hack. The rigidity of its frame, the excellence of the front fork, and the balance of the engine made it far more comfortable to sit than most babies are. It has proved a glutton for work. It always started in a yard or two from the stable door, except when damp on one occasion affected the magneto bellcrank. On taking the road it was usually opened up to the fastest pace of which circumstances permitted, and no part of it other than the sparking plug ever resented five miles on two-thirds throttle; after such a spin it would feel a little weak in top gear work uphill, but would instantly recover if the low gear were thrown in. On its low gear it is perfectly capable of climbing grades of 1 in 6, even when it is very hot. The special two-stroke plugs made by the Lodge and Sphinx people suit it well, but I got the best results from Lodge racing plugs after I had mastered its lubrication. I do not recommend these plugs until the oiling is correct, as they are not designed to burn oil off their points, and are none too easily cleaned if accidentally sooted. As I normally drove my machine very hard, the usual petrol consumption did not work out at much better than 60 m.p.g., though on several occasions I got 80 m.p.g. in pottering work at a speed rarely above the legal limit.

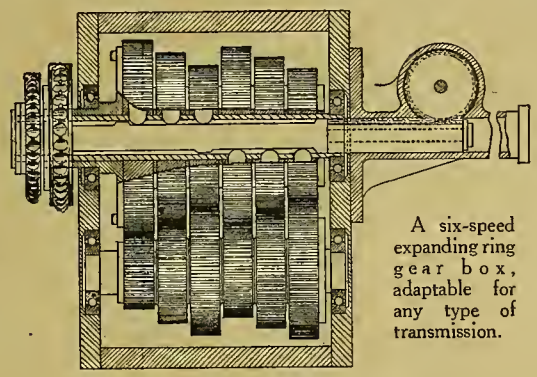
Two Winters on a James Two-stroke.—

With petroil lubrication carburetter flooding is apt to make the fuel consumption artificially high, unless oil is carefully filtered; small impurities in the oil lodge in the needle valve seating and prevent the needle from closing. Given a suitable sparking plug, the running of the little James is hard to beat. In the matter of design, I can only name two points for consideration. The transmission is undoubtedly unusually simple and efficient, but it is the reverse of accessible, and owners would be well advised to content themselves with removing the cylinder when tuning up; if they attempt to take the engine completely down they will regret their temerity. The other defect is almost universal on two-strokes. The head of the cylinder comes so near the middle tube of the frame that there is only comfortable clearance for a midget sparking plug. Beyond question two-stroke engines benefit from the use of big, well-cooled plugs, and especially from the addition of such patent plug radiators as the Fletcher. With greater clearance, the use of such plugs and accessories would be easier. It must, however, be granted that the middle frame tube is missing from many lightweights, and many such frames are insufficiently rigid for strength and comfort. IXION.

EXPANDING RING GEAR.

THE gear box here illustrated is the patent of Mr. Edward Davies, Queen Anne's Chambers, S.W., and represents an attempt to carry into practice an expanding ring friction gear giving more than two speeds. The pinion wheels on the primary shaft each contains an expanding ring clutch, the operation of the rings being by a central rod, free to slide horizontally, and having two cams, by which engagement and disengagement are effected.

The general principle of the gear is shown in the inventor's drawing, which represents the device in its extreme form, giving six speeds.



A six-speed expanding ring gear box, adaptable for any type of transmission.

In a modified form the device might be adaptable to motor cycle use, and, if brought within reasonable limits as regards weight and size, would undoubtedly prove a very pleasant gear to handle.

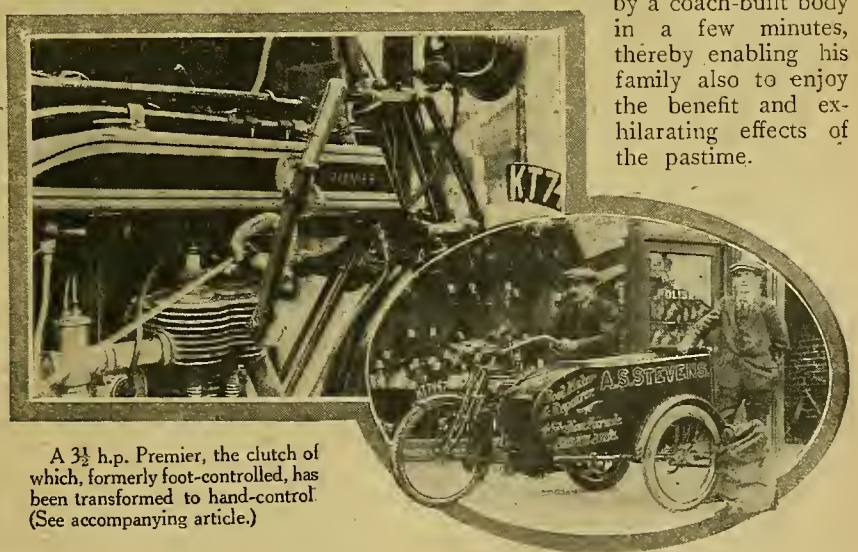
The method of operating the clutches appears to be the only point suggesting possible novelty. It will be observed that the cams come into operation alternatively, thus reducing the necessary movement of the actuating rod. The less movement on this rod, indeed, the better, for some leverage would be required to overcome the friction on the cam faces. The drawing is purely diagrammatic.

MOTOR CYCLES FOR THE LAME.

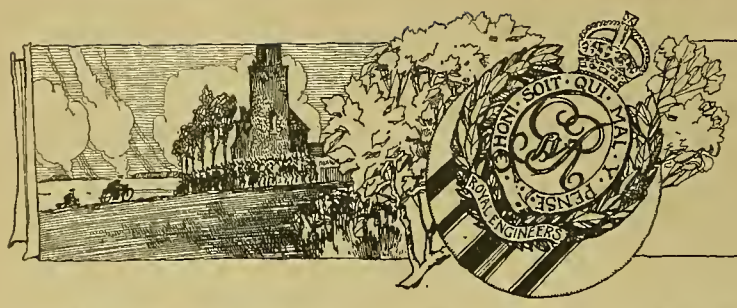
WE have many times commented on the possibility of motor cycle and sidecar driving for lame riders. There are, unfortunately, many who will be prevented from participating in the pastime in its more strenuous forms when peace arrives, but those who have received severe injury need not lose hope of ever again enjoying the pleasures of driving a motor cycle. Many devices are being evolved whereby full and complete control of the sidecar will be possible even by a one-armed man, the matter being still simpler if only one leg be lame or lost.

We have received from Mr. Arthur S. Stevens a letter in which he states that he had at one time never thought to have the pleasure of riding a motor cycle, being lame in his right leg, but to-day he can ride and drive anywhere, and is able to use his machine for business purposes. The machine originally had the usual foot clutch control, but Mr. Stevens has now arranged for control by hand, as will be seen from the photograph. The control is handily situated on the off side of the machine, attached to the tank tube, and is of substantial size—an advantage in that a gradual engagement is possible.

Mr. Stevens has arranged the trade box carrier so that it can be taken off the chassis and replaced by a coach-built body in a few minutes, thereby enabling his family also to enjoy the benefit and exhilarating effects of the pastime.



A 3½ h.p. Premier, the clutch of which, formerly foot-controlled, has been transformed to hand-control. (See accompanying article.)



MILITARY NOTES.

Notes from the Various Fronts. "The Motor Cycle's" 11,264 Recruiting Applications.

OVERSEAS SINCE 1914.

W SPENCER PERCIVAL, formerly connected with the London depot of Humber, Ltd., who was an official observer in the last A.C.U. Six Days Trials, and won a double journey gold medal in the London-Edinburgh-London run, has been in France with the British Red Cross service since October, 1914, and is now making application for a transfer as a despatch rider.

MOTOR CYCLIST AS WORKSHOP OFFICER.

LT. REGINALD G. PARKER, A.S.C., M.T., formerly of St. Ives, Hunts, was married last week, at Bridlington, to Miss Evelyn May Simpson. Lt. Parker will be remembered by readers as a competitor in the Paris-Nice trial, and figured in other contests. He will return to his workshop company in France after the honeymoon.

TRADE AFTER THE WAR.

AN A.S.C. officer on the West Front, formerly connected with the motor trade in the Midlands, in the course of a letter to us, remarks:

"All the boys here read *The Motor Cycle*, and I can tell you we appreciate it immensely, and especially your efforts to help the trade out for business *après la guerre*. Believe me, there will be a few of us looking for good jobs with fat screws attached when this job is over, but goodness only knows how many of us will get them. Anyhow, we shall just have to 'wait and see,' to quote an ancient and rotten policy."

ADVENTURES OF THE M.C.C. SECRETARY.

WRITING from Alexandria Hospital, Maitland, Cape Town, to the Editor of this journal, Col.-Sgt. Southcomb May, former secretary of the Motor Cycling Club, says:

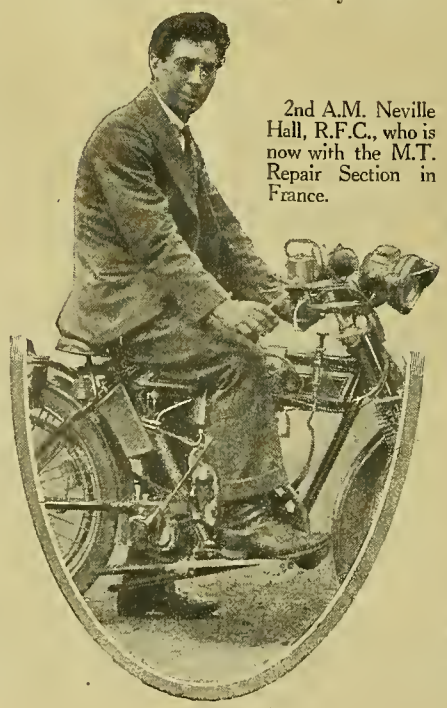
"It is very hard to get any news of what is happening in G.E.A. out here, but apparently my chums of the Gold Coast Regiment are still not far from where I left them. We had a pretty easy time on the march down as far as the Wami River, and generally had a grass shelter to sleep under, though I very frequently slept outside in preference. The men run these shelters up very quickly, and they vary in elaborateness. We only had one wet night, and, of course, on that occasion for some reason or other we were shelterless with the exception of a ground sheet. The next day we had a rainproof shelter built, and, of course, it did not rain. The following day we moved on about eight miles, and my company were camped on top of a hill with about a 1 in 2 gradient. After that we took to the mountains until we finally bumped into the Germans. I got through nearly 3,000 rounds with my Vickers gun, and that was after a march of 200 miles without seeing a shot fired."

It should be added that Mr. Southcomb May, though recruited for the M.M.G.S., answered with five others a call for volunteers for the Gold Coast, as at that time he saw no immediate prospect of Overseas service with the M.M.G. All were accepted, and a few weeks later landed at Mombasa, calling at Cape Town and Durban, and thus seeing something of South Africa on the way.

A LIGHTWEIGHT EXPONENT IN FRANCE.

WE have received from France a most interesting letter from Neville Hall, who will be recalled as an exponent of the O.K. lightweight machine, his most notable performance being in the gruelling Six Days Trials of 1914. His was the only miniature to finish, and the other competitors were so impressed by his plucky exhibition that a petition was signed to present him with a special gold medal. Hall has served two years in the R.A.M.C. and eighteen months in France. For some time past he has been anxious for a transfer, and wrote us on the subject many months ago. He is now in the Royal Flying Corps as a second-class air mechanic, in which section he naturally feels more at home by reason of his great interest in motor vehicles, and particularly his ability to extract the utmost efficiency from small engines. He is at present a fitter in a M.T. Repair Section. Hall says:

"It is good to get back to the old game again. Our division had been through most of the Somme dust from July 1st right up to Thiepval, which we took on September 26th. It was there that I first saw the Tanks and also got in the way of a bit of Boche H.E. Luckily only a slight wound, in fact I did not even get to the base. Two Christmases over here is just a bit too much for anyone unless he is an absolute glutton. The sergeant in our shop is Sydney George, of Indians, and we had Capt. A. Mackenzie Cott, once owner of Big Ben, over us for a fortnight."



2nd A.M. Neville Hall, R.F.C., who is now with the M.T. Repair Section in France.

"THE MOTOR CYCLE'S" WAR WORK.

SINCE the beginning of September last, at which time the Editor of *The Motor Cycle* ceased to recruit direct for Army motor cyclists and car drivers, 659 letters applying for advice with regard to enlisting in the various specialised sections of the Services have been received and dealt with. In many instances men have been examined technically and a certificate issued at the special request of the recruiting authorities. The applications mentioned bring the total number of enquiries on recruiting subjects received since the war began to 11,264.

SPECIAL BADGE FOR TANK OPERATORS.

AN Army Order states that a special badge has been approved for the *personnel* of the Machine Gun Corps, Heavy Branch ("Tanks").

The badge will be worn on the right upper sleeve of the service dress jacket by all ranks. In the case of non-commissioned officers who wear chevrons above the elbow it will be worn immediately above the chevrons. Approval has also been given for the introduction of new badges for First Class Lewis and Hotchkiss gunners.

ILLNESS AND THE SEVERE WINTER.

WE much regret to record that L.-Cpl. W. I. McGhie, a well-known Coventry journalist, who joined the Machine Gun Corps, Heavy Branch ("Tanks") last June, died last week in a French hospital after suffering from bronchitis and asthma.

ONE OF THE ORIGINAL D.R's.

LT. RALPH MANSFIELD, nephew of Lord Sandhurst, who was married at Sheringham on Thursday last, volunteered at the start of the war as a despatch rider, and did excellent work. He has since received a commission in the Royal Engineers.

MENTIONED IN DESPATCHES.

LAST Thursday's *Gazette* contained the following names of motor cyclists mentioned in despatches in General Smuts's report of the East African campaign :

South African Motor Cycle Corps.—Lt.-Col. J. McI. Fairweather, D.S.O., Lt. H. E. Jackson, Temp. Lt. H. A. E. Hall, Sgt. J. Coles, and Sgt. H. W. Watts.

South African Motor Despatch Riders' Company.—Cpl. J. Kloppert, Cyclist W. Israel, Sgt. F. S. Johnstone, Cyclist P. Smith, Cyclist S. Gibbins, Cyclist D. Stewart, Cyclist L. C. Ratcliff, Sgt. J. J. Smith, and Sgt. C. D. Bulman.

THE TANKS ON THE FILM.

CORRESPONDENTS report great enthusiasm in the provinces where the official film of the Tanks is shown. There is quite a hubbub of excitement when the Tanks are announced, and there is no doubt that they have struck the popular imagination. The men who operate them are regarded as heroes, and quite rightly, too. Many who have seen the films were surprised to observe that the men in the Tanks wear leather helmets very similar to those used by racing motor cyclists. The helmets are, of course, to prevent the occupants of the Tanks bumping their heads on projecting machinery inside the Tank when traversing rough ground. There is comparatively small space available inside a Tank.

At the picture house the writer attended a member of the audience was overheard explaining to a companion how the word "Tank" originated. "The Government started to make these Tanks at the outbreak of war," so he affirmed, "and to put inquisitive people off the scent they were described as 'Water Tanks.' The ruse was quite successful," the youthful informant added. As a matter of fact the incident reminds us that the men of the Tanks had an "official" trick played upon them during their training at the secret camps. So that the intentions of the Army authorities should not become known, the first batch of Tanks had clearly emblazoned upon their sides different Russian names, which at once, perhaps naturally, gave rise to the rumour that they were intended for operations on the Russian front. More than one recruit whispered to us that Russia was whither he was bound.

MOTOR CYCLIST D.R.'s OF THE TANKS.

Severe weather is being experienced in France, but throughout our doughty men must "carry on." The photograph, depicting very wintry conditions, was sent to us by Gr. G. Pattison (left) and Gr. Brown (right), both despatch riders of the H.B., M.G.C.—the Tanks

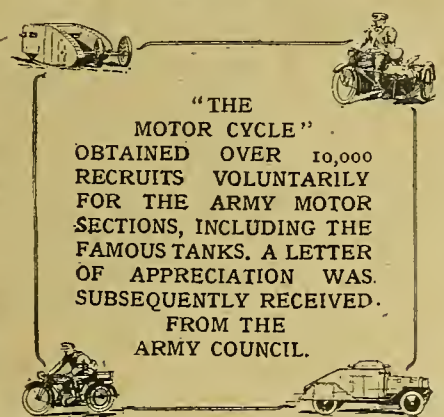
A SIDECAR COMBINATION WANTED.

THE Church Army is urgently in need of a good motor cycle and sidecar for organising work in connection with the C.A. Flying Squadrons. In the *Church Army Review* the Editor writes to the effect that such a gift would "be an excellent opportunity of putting to good use a machine disused, temporarily or permanently, on account of petrol restrictions." Any kindly response will be most gratefully received by Capt. Carter, 56, Bryanston Street, London.

A TRIALS RIDER ON MILITARY MACHINES.

A LEADING trials rider at the Front comments as follows as the result of extended experience with the machines allotted to him :

"When will makers of all military machines realise that two speeds are not enough, and that a handle-bar controlled clutch is a necessity? Half an inch clearance between tyres and guard is not enough by inches, and, again, the front rim brake is worse than useless out here. It should be remembered that in the war zones motor vehicles get the maximum of riding with the minimum of attention, and, all things considered, they stick it wonderfully. It is the little things that worry one, not so much radical faults in design."



"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS TANKS. A LETTER OF APPRECIATION WAS SUBSEQUENTLY RECEIVED FROM THE ARMY COUNCIL.

FORMER HUMBER TRIALS RIDER.

A. G. FENN, whom we last heard of in Egypt, is at present in a Midland convalescent home for officers suffering from a bad attack of rheumatism in the feet.

Average Prices of Second-hand Machines.

WE give below the average prices of second-hand models offered for sale in *The Motor Cycle*. Difficulty in obtaining a sufficient number of one particular model often arises, owing to the fact that many advertisers omit some of the most essential details.

Make.	Year.	H.P.	Average for last week.	Latest weekly average obtainable.
A.B.C.	1914	3½ T.T. 3-sp. s/car	£70	—

WAR WORK AND LADY MOTOR CYCLISTS.

MACHINING A CYLINDER.

TWO WINTERS ON A TWO-STROKE LIGHTWEIGHT.

The Royal Automobile Club.

It has been officially announced that the Royal Automobile Club, instead of being requisitioned as a Government office, will be allowed to continue as a club for Overseas officers.

To Develop British Petroleum.

To develop new sources of petroleum found in the British Isles, Sir Boverton Redwood is taking charge of a research section for the Ministry of Munitions. Sir Boverton Redwood is petroleum expert to the Government, and has long been associated with the R.A.C. Technical Committee. Sir Boverton stipulates that he will not accept remuneration for his services.

Few Second-hand Machines in France.

A French reader seeking our advice on the purchase of a second-hand motor cycle mentions that he has been offered in Paris a 1914 T.T. B.S.A. with three-speed gear box at £64, a 1913-14 T.T. B.S.A. with single gear £56, T.T. Douglas with three-speed gear box £72, and a Manx Rudge 1913-14 model £80. These prices give some idea of the high figures that the few British second-hand motor cycles available in France now command.

Youthful Genius.

Regularly drawings of motor cycles are sent us by proud parents as examples of the budding genius of their small sons. We certainly do not wish to discourage amateur efforts, but the circumstances are rather reminiscent of the unfortunate artist who, having lost both arms, continued to paint with his feet. Admittedly his pictures were good, considering he had done them with his feet, but the question arose, Why do them at all?

More Road Manglers.

The Local Government Board has recently issued an Order that "the driving wheels of an agricultural locomotive which are shod with diagonal cross-bars may, while the locomotive is being used on frost-bound roads, be provided with studs."

This amendment of the Act is, of course, owing to the long cold snap, the condition of the roads in many districts being such that the greatest difficulty has been experienced in moving heavy locomotives owing to wheel slip.

The Practical Motor Cyclist.

We hear of three motor cyclists who have evolved special types of aeroplane engines so promising in design that they are being considered by the Army and Navy experts. It has often been remarked with real truth that the motor cycle is the finest schooling a motor engineer can receive.

Adapting Zeppelin Practice.

In December last our contemporary *The Automobile Engineer* published a full description of the power unit used for the propulsion of Zeppelins, and a reader now suggests that the system employed on these engines for cooling the lubricating oil, the big end bearings, and indeed the whole interior of the crank case, might advantageously be adapted to motor cycle engines. On the Zeppelins a ventilating cowl, facing the direction the airship is travelling, scoops air into a big manifold, from which pipe connections convey the cooling blast to the crank case bearings. The air is drawn out by a second manifold, which increases in diameter as it extends towards the rear, where it terminates in a similar ventilating cowl facing backwards. The greater the air resistance the greater the load on the engines, while the strength of the cooling draught increases, of course, proportionately, yet we fear that the system could not successfully be applied to motor cycle engines on account of the dust in the atmosphere so near the road. The oily interior of the crank case would indeed have a tendency thoroughly to filter the air.

Interest in Motor-assisted Bicycles.

Our illustrated description of the Simplex motor unit for attachment to pedal cycles has created great interest, judging from the enquiries which have followed the publication of the article.

A 'Varsity despatch rider of a Douglas motor cycle attached to Headquarter Staff scribbling a message in which a French poilu is interested. The scene is quite near the firing line in France.

The National War Funds.

At the week-end the principal war funds stood as follow :

The Prince of Wales's Fund (distributed £3,529,719)	£6,030,105	0	0
British Red Cross Fund	6,135,022	0	0
Tobacco Fund	125,290	0	0

No Petrol—No Licence Needed.

In view of the possible petrol position in the spring, *The Motor Cycle* urges that the authorities cannot justifiably retain the whole of the 1917 licence fees paid during the month of January.

The Balance of V Twin Engines.

A letter published from Mr. Osborne de Lissa, of the M.A.G. Engine Co., contains the statement that the company has on test an M.A.G. engine, a V twin of 45°, which is so well balanced that at 3,000 revolutions it will run without being bolted down to a bed. This is a test which, we believe, only flat twins have hitherto succeeded in passing.

The Refund of Licence Fees.

An authority in the motor world, to whom we suggested that motorists were entitled to a refund of a proportion of the licence fees paid, replied that he did not consider that the Treasury would consider such a rebate because—*(a)* There is no knowledge as to the period for which petrol licences will be non-renewable, and the restriction may be removed in three months. *(b)* It would be too much trouble to check whether a man had a just claim for supplies.

The Motor Cycle not a Dangerous Vehicle.

According to Rochester, N.Y., there were 1,054 accidents caused by vehicles of all types during 1916, of which 906 were slight and 48 fatal. Of those that did not result fatally, 454, or more than 50%, were caused by automobiles; almost one half of the fatal accidents—21 out of 48—were also caused by motor cars. Next to the motor car the tramcar was the chief offender, there having been ten fatalities and 154 lesser accidents due to the tram. Horses and horse-drawn vehicles caused the deaths of five persons and injuries to 84. There were all told 84 motor cycle accidents, considerably less than 10% of the total, and of these only one resulted fatally.

Imports and Exports.

Instead of a blank, or at least a very insignificant total, against the amount of imports of motor cycles for January, we have the remarkable sum of £16,218. It was understood that imports of motor cycles were to be prohibited from last March, yet the imports during January were *more* than those in January of 1915, before prohibition was spoken of. This is a remarkable state of affairs. We exported 872 motor cycles last month, to the value of £45,454. The value of parts, however, is greatly in excess of the January, 1916, figures, being £33,676 against £31,602.

The January exports of motor cycles and parts for the last three years are as follow :

1915.	1916.	1917.
£45,696	£70,065	£79,130

PETROL IMPORTS.

There has been a huge increase in the quantity of petrol imported over the previous January's amount. Figures :

Jan., 1915.	Jan., 1916.	Jan., 1917.
Gals.	Gals.	Gals.
6,984,339	6,985,279	13,001,740

9,000,000 gallons more petrol were imported during January, 1917, than in December, 1916. No doubt the difference is accounted for by the sailings of the tank ships being uncertain.

Duty has been paid on 8,986,719 gallons during the month ended January, 1917. It may be of interest to know that 18,483,000 gallons of petroleum and other lamp oils were imported during last month.

Substitute for Petrol.

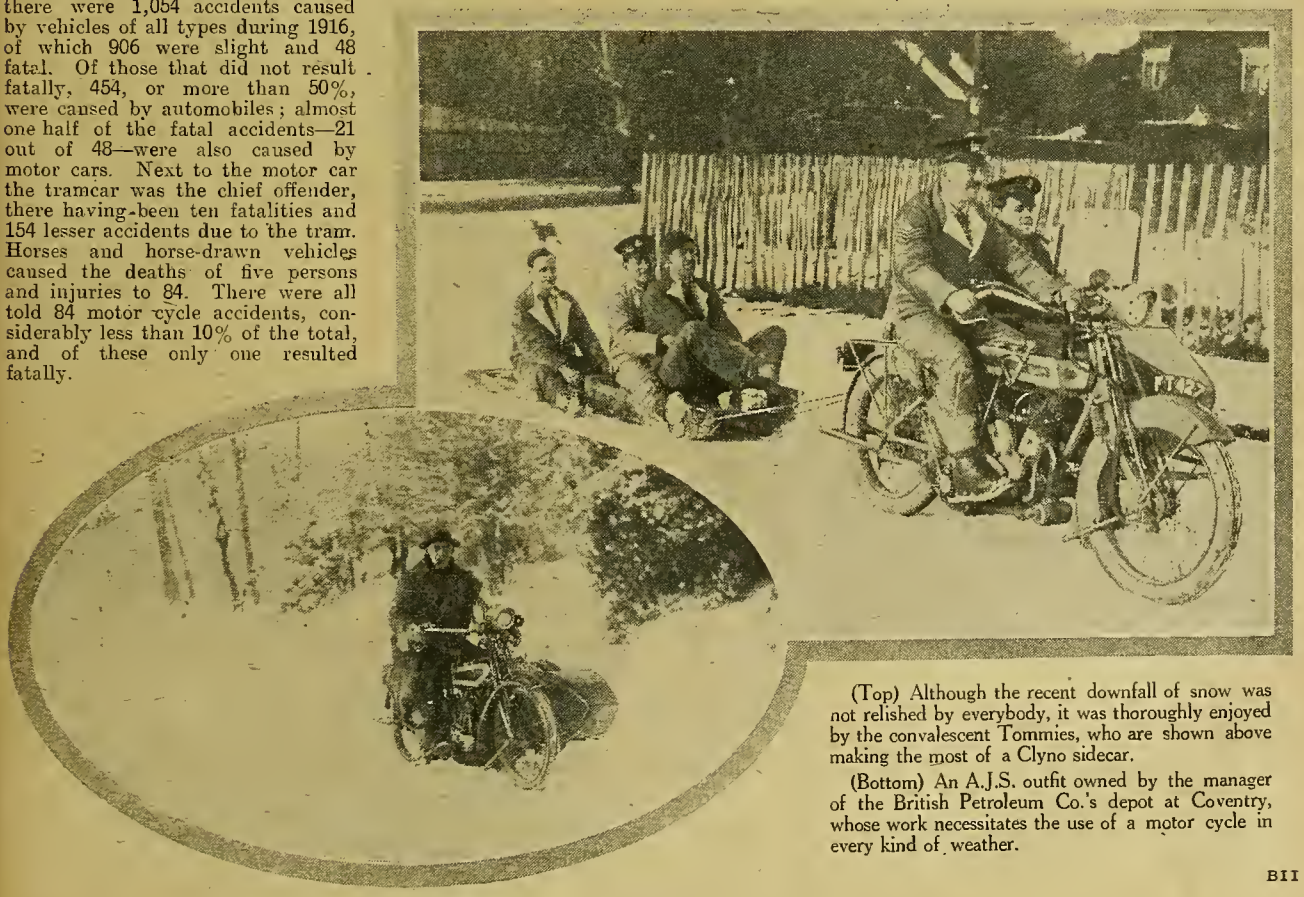
The latest substitute is Vaporine, handled by Mr. Hugh Gibson, the famous sidecar driver, who was formerly with the Clyno Engineering Co.

Petrol for National Workers.

It is gratifying to know that motor volunteer sections and motor ambulance corps supply petrol to their members, and a motor cyclist who is doing work of this kind can feel, while he is enjoying his favourite pastime, that he is doing some good for his country. In this connection we may mention that the National Motor Volunteers, Room 5, The Polytechnic, Regent Street, London, W., are seeking the assistance of quite a number of motor cyclists, of which they are very short, so here, at least, is one opportunity of which Metropolitan riders may take advantage.

Mail and "The Motor Cycle" Adrift.

It is quite conceivable that letters from Overseas readers intended for *The Motor Cycle* may not in all cases reach their destination, on account of the activity of submarines, the Hun knowing no law, even passenger ships carrying mails being sunk without warning. For the same reason, copies of *The Motor Cycle* posted to subscribers abroad may, in some instances, fail to reach their destination. The publishers of *The Motor Cycle* give notice that, as far as possible, they will endeavour to replace any copies lost if application be made reasonably early, mentioning date of the missing issue.



(Top) Although the recent downfall of snow was not relished by everybody, it was thoroughly enjoyed by the convalescent Tommies, who are shown above making the most of a Clyno sidecar.

(Bottom) An A.J.S. outfit owned by the manager of the British Petroleum Co.'s depot at Coventry, whose work necessitates the use of a motor cycle in every kind of weather.

PETROL - PARAFFIN MIXTURES.

A Method of eking out Petrol Supplies.

THE writer is one who studies economy wherever possible. In view of the shortage of petrol I turned my attention to paraffin as a substitute, and my experiences may interest other motor cyclists.

I am a rider of a 3½ h.p. of well-known make, which at present is rather difficult to obtain owing, I think, to the demand of the War Office, etc. It has horizontally-opposed cylinders, two speeds and clutch, is fitted with a coachbuilt sidecar, and after eighteen months' usage, and covering about 3,000 miles, it is still an ever-ready mount.

Experiments with Paraffin.

I have always used petrol alone until 1916. At the beginning of last year I took the engine down, and was surprised to find scarcely any carbon deposit on the top of the pistons and cylinder heads, and that the rings were as free as ever they were. This I thought might possibly be due to my having the magneto fairly well advanced, say about a half or two-thirds, therefore giving a clean explosion, though this, of course, would slightly increase the heat of the engine. When petrol became expensive I considered the use of petroleum. I started experiments on a twenty-mile run with fairly steep hills, but found, with a mixture of one-third petroleum to two-thirds petrol, that to get up speed was more difficult, especially after slowing down in top gear and then trying to pick up again; also that popping and back-firing in the carburetter occurred fairly often, and that blowing out through the air inlet was quite a black smoke, which gave me the opinion that my engine was getting more carbon deposit than with petrol only.

110 Miles on 1½ Gallons.

Still out for economy, I had another trial. This time I made a mixture of one quart petroleum to one gallon of petrol, and filled my tank, which holds one and a half gallons, and then took a run, with my wife and child in sidecar, over the Mendip Hills from Bristol to Castle Cary. This is twenty-eight miles direct from our city *viâ* Pensford, but the road I took was *viâ* Keynsham, Hallatrow, and Shepton Mallet, which increases the distance about four miles or so. On my return journey I went through Bruton, which is three miles from Castle Cary, making the total distance about sixty-five miles. The running of my machine was certainly quite even and there really seemed to be more power, and I could take full air at good speeds, just the same as with petrol.

Later we took a spare tin of petrol mixture, but did not refill the tank, as I was anxious to see what mileage could be done, and set out for Cheddar *viâ* Burrington Coombe, taking the end of the Mendips again. The engine travelled splendidly all the way, taking hills quite easily. We returned through Axbridge and Langford, over the noted Red Hill, which is long, steep, and with plenty of ruts, running down the steepest part of it. Then we turned from the main Bridgwater Road and went through Brockley Coombe, returning home by the lower road. The ride was very exciting, as we expected to run our tank dry every minute; but we finally arrived home without replenishing the tank, though it was practically drained dry. This trip was about forty-five miles, and with the previous run makes about 110 miles on one and a half gallons, an average of well over seventy miles to the gallon, and only going in bottom gear about twice on each journey. This with a coachbuilt sidecar, with wife and child as passengers, say about 10 stone, and myself 10 stone, I consider good, and is a much higher mileage than I have done before. The cost of this mixture works out at about 2s. 4d. a gallon, a saving of 5d. a gallon against No. 2 petrol—not a great margin, but it is a consideration to those of limited means. The weekly saving, however, will pay the storage bill, which is something at any rate.

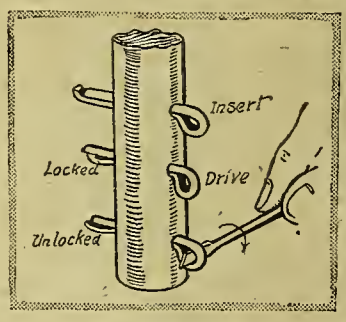
My mount has given every satisfaction, and up till now has only needed the attention of myself. I am no mechanic, and have only the knowledge that I have gained chiefly by reading *The Motor Cycle*. I have taken most of the steepest hills round about Bristol, such as Dundry, Rownham, Red Hill, etc. My machine romps up all of them, and I cannot say that I long for a heavy combination. What I cannot master on top gear I can easily accomplish with the bottom, though on long hills that are rather steep a third gear would be a great advantage, as it would mean that the hill could be climbed more quickly.

C. T. HILL.

[*The use of substitutes has been exhaustively dealt with in "The Motor Cycle" by helpful articles, and subsequently by readers who have related their actual experiences, and described the design of vaporisers used.*—ED.]

THE HAMMERLOCK SELF-SPRINGING COTTER PIN.

MESSRS. BROWN BROTHERS, LTD., 15, Newman Street, London, W., have lately introduced the Hammerlock self-springing cotter pin, the points of which are tapered quite close together, so that the cotter pin may be pushed straight through the hole intended. To lock it it should be hammered on the head until the points are of equal length; then it is necessary partially to flatten out the eye, and force the shorter or straight branch forward, so that its end will ride up over the upturned point of the other branch, thus automatically separating as well as locking the point rigidly into place. To remove the cotter the point of a screwdriver, the tang of a file, key, or any thin tool should be inserted in the eye and twisted in the direction indicated by the arrow so as to return the short shank to its original position. When this has been done the cotter pin can be removed with the aid of the fingers.



A self-springing cotter pin of novel design.

The Petrol Control Committee regret to announce that they are no longer able to consider applications for the renewal of *existing* full-duty motor spirit licences for private motor cars and motor cycles, unless the holder of the licence is engaged upon work of national importance and the continued use of a motor car or motor cycle is essential for such work.

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

WHO SHOULD HOLD DRIVING LICENCES?

Sir,—With reference to this subject, having driven various cars and motor cycles for a period of over ten years, and being partially deaf, I consider that I am qualified to make a statement on the matter.

I note that your reader, Mr. Hitchcock, asserts that only the sound of a horn can, in many cases, avert an accident. This I can understand when a cart or pedestrian is concerned, but in the case of two motor cycles or cars his idea is absurd. Has he never read of any motor accidents in which both parties swear that they blew their horns, but neither heard each other? in fact, such a case occurred quite recently, in which the judge stated that he considered it to be very difficult to hear another car when travelling in one's own.

I find that the majority of motor cyclists seem quite unable to hear an overtaking car or motor cycle until it is practically on top of them, regardless of any amount of horn-blowing. This is easily explained by the noise of their own engine and the rushing of wind past their ears.

Your correspondent's fear of runaway horses I can only characterise as sheer piffle; certainly I have never met with one in my lengthy road experience, and, in fact, have never been inconvenienced by my defect.

In conclusion, it is rather a good thing for Mr. Hitchcock that his three tests of a driver are not carried out before granting licences, for after reading the whole of his letter one is forced to think that he would certainly fail on the third.

R. VERNON ESNOUF,
Manager, The Cardiff Motor School.

Sir,—The action of the Northamptonshire Licences Committee seems based on an old and popular contention that because a man cannot see or hear he is a danger and a nuisance when using the roads. This is the theoretical conclusion, and would not be borne out by facts.

I am stone deaf myself, and I have cycled for years and motored for five years, with cars as well as motor cycles, without danger to myself or to others, by day and by night, and often on the byways of the country, where hardly two cars could pass.

The deaf motorist cultivates his other faculties, is extremely cautious, and the possessor of an acute mind. Above all he obeys the rule of the road.

If all motorists used the roads as the deaf man does there would be fewer accidents. It seems the usual habit of many motorists to take corners wide as long as no warning is heard.

JOHN OSWIN.

[Many letters, voicing the same sentiments on this subject, have been unavoidably held over owing to want of space. —ED.]

Sir,—"M.C.S." sees no reason why he, who has only one eye, should be considered an incompetent driver. Perhaps he is unable to see this, because he has only one eye. I have two and can see a very good reason, viz., persons with only one eye cannot judge distances. I have only been in one collision between vehicles, and in that instance the driver of the other vehicle had only one eye, and misjudged his distance from me.

It is, of course, a great misfortune for "M.C.S.," but that is no reason why he, and other persons similarly afflicted, should be allowed to be a danger to themselves and to other road users, vehicular and pedestrian.

A. L. GRAY.

HEATING THE INDUCTION PIPE.

Sir,—(1.) "Ixion" states that the *longer* the induction pipe the better the carburation as regards power, acceleration, and economy—three real good points. In the latter part of his remarks on this subject he states that the single-cylinder engine would not show a *less* efficiency if the inlet pipe were a foot long if heated. The essential point to me is, would the single-cylinder with a properly heated *long* induction pipe show *more* efficiency?

(2.) Heating the induction pipe: Will Mr. John Hawes be kind enough to state how the *ends* of his copper jacket were sweated. Probably to the induction pipe. A small sketch would be of great assistance. I wish to try this (Mr. Hawes's) method, as a saving of twenty miles to the gallon is worth cultivating.

(3.) "Heating the Carburetter," by M.A., LL.B., M.B. This gives a very clear sketch of the heating system, but the result, being the same as without the hot air supply, puts me in the same position as the Novice in "The Critics."

I shall feel obliged both to "Ixion" and Mr. Hawes for any assistance they will kindly give.

OLIVER.

Canonbury, N.

STARTING ON ACETYLENE.

Sir,—We note the letter written by Mr. F. C. Lees, which appeared in your number of the 1st inst.

We do not wish to use strong language, but we think it really necessary to point out that this letter from Mr. Lees is of so extraordinarily inaccurate a nature that we are really at a loss to know what object Mr. Lees had in writing it, unless his statements were due to sheer ignorance.

He infers that anybody using acetylene in an internal combustion engine is liable to a fatal accident, and he also infers that fatal accidents have been caused by using acetylene in this manner.

Can he point out one single fatal accident due to this cause?

As a matter of fact, acetylene behaves in an internal combustion motor in exactly the same way as a mixture of petrol vapour and air or of coal gas and air. The only difference is that the calorific value of acetylene is higher; in other words, more air is required and less gas. It seems to us that a very superficial knowledge indeed is necessary to reduce the proportion of acetylene.

Can Mr. Lees produce one single instance of the top of a cylinder having been blown off through using acetylene? It is possible that an isolated case may occur—although there is not one in our records—but, on the other hand, we can produce hundreds of cases where acetylene has been used successfully for years for running gas engines, for instance, at country houses.

The most astounding statement of Mr. Lees is, however, that the making of a mixture of oxygen and acetylene is prohibited by law. This shows the extent of Mr. Lees's knowledge, and it may interest him to know that there is not a Government dockyard, nor a munitions factory of any importance, where oxygen and acetylene are not mixed together on a very large scale for the purpose of welding.

There is not a Dreadnought or other vessel of war, or mercantile steamer, or aeroplane, or torpedo built to-day without the aid of the oxy-acetylene blowpipe, which works with a mixture of acetylene and oxygen.

The final paragraph of Mr. Lees's letter, "I would not on any consideration allow acetylene to be used in any case

where I might be able to prevent it," shows the value of his opinion, or of his experience, seeing that his opinion is directly opposed to that of every scientist of note in the kingdom.

For THE BRITISH ACETYLENE AND WELDING ASSOCIATION,
R. G. LUCAS, Secretary.

Sir,—With reference to broken connecting rods and cylinder heads, I have seen and heard of numerous cases when using petrol. I might say that while scanning the morning paper recently I read of a man and boy being killed through petrol vapour becoming ignited; so much for petrol. Now, if the tank of the car in question had been filled with paraffin and started up with acetylene, this catastrophe would not have happened. With petrol, of course, you carry the high explosive with you wherever you go, and in some instances sit on top of it. Mr. Lees, I think, has made a slight mistake in tackling the danger question. H. G. PASSEY.

CAN THE LIGHT CAR EQUAL THIS?

Sir,—With reference to Mr. J. Horswill's letter in your issue of January 25th *re* his Powerplus Indian combination, if this should catch his eye, I should very much appreciate particulars of the improvements he has made, viz.: Front guard side shields, rear ditto, leg shields, and the extra air slide, as I am at present riding one of these models.

G. A. ROBERTS.

BEARING PRESSURES AND LENGTH OF STROKE.

Sir,—In the recent discussion on bearing pressures with reference to long and short-stroke engines, may I venture to point out that the matter is not one of simple calculation such as your contributors seem to unite in thinking.

During the course of eighteen years' experience in designing various mechanisms, I have had to unlearn many of the conventional ideas regarding stresses and bearing pressures. In all mathematical computations of bearing area that I have come across it has been customary to regard the journals as perfect cylinders which fit the bushes evenly from end to end, due regard being paid to the maintenance of a film of oil between the bearing surfaces.

It surely must be evident to any thinking person that in the average motor cycle crankshaft, supported on two bearings only, and built up of no fewer than five separate main units, the centre line of the crank pin cannot describe a truly cylindrical path. The centre line will usually lie at an angle, however slight, with the axis of the crankshaft in either or both planes. In the first case the figure generated by the crank pin centre line will be the surface of a cone; in the second case it will be a portion of a hyperboloid. This will cause an alternation of pressure between the two end portions of the bearing, theoretically amounting to an infinite pressure at the extreme edge of the bearing if no lubricant were present. The presence of the lubricant acts as a yielding medium between the journal and the bearing, and tends to cause a diminution of the intensity of pressure towards the ends of the bearing.

When under load, owing to the usual overhang of the pulley or driving sprocket, severe bending stresses are induced in the crankshaft, which may alternately increase or diminish the alternating pressures at the ends of the crank pin journal by increasing or diminishing the initial distortion of the crankshaft. As this is the case, I fail to see the object of wrangling over a matter of 15% theoretical difference in crank pin bearing pressures, when the difference in bearing pressure from the centre to the end of the selfsame crank pin may vary well over 200%, depending upon the initial accuracy of the workmanship and the stiffness of the crankshaft. Since the variation in pressure depends on the error in parallelism of the crank pin with the crankshaft expressed as an angle, it follows that the most accurate crankshaft will have the longest bearing life. The accuracy of a built-up crankshaft depends mainly upon the spacing of the holes in the flywheel and their squareness with the same. Consequently, for the same error in spacing a long crank pin will be nearer parallel with the crankshaft than a short one. At the same time, owing to its length there will be more distortion of the crankshaft under load. So that, all things considered, a short stout crank pin is preferable to a long slender one. It seems to me there should be no great difference between the long and short-stroke engines in the respect of actual *not calculated* bearing pressures, and in my own experience I have found very little difference in the bearing life of crank pins of both long and short-stroke engines.

I have in mind a 1911 Bradbury (89 × 89 mm.) engine, which has run up to date over 40,000 miles, and has lately been rebushed for the third time.

A 1912 4¼ h.p. Precision (89 × 96 mm.) up to two and a half years ago had run 18,000 miles in my own hands without rebushing, and is still running with, I believe, the same bearings.

A 1913 Triumph (85×88 mm.) was rebushed three times in 12,000 miles.

A 1913 Norton (82 × 120 mm.) is still running after 30,000 miles, and has been rebushed once.

A 1915 Norton (82 × 120 mm.) in my own hands did 12,800 miles until twelve months ago. Since then it has done a further 8,000 miles, and has only just been rebushed.

My present machine, a 1916 Norton (82×120 mm.), has been running for the last twelve months, and the bearings are practically as good as new.

All the above machines have led a far more strenuous life than might be inferred from the mileages only, since they have been used with sidecar almost solely for gear testing purposes over the hilliest roads and tracks it has been possible to find in the Peak District and the North of England. It will be seen that, as far as the crank pin bearings are concerned, there is practically nothing to choose between them. In the case of the Triumph it is only fair to say that a 3½ h.p. machine had to be constantly over-driven, and even then was not sufficiently powerful to give any definite results in testing gears. The long-stroke machines showed to particular advantage in long stretches of low gear work over abominable surfaces, keeping most wonderfully cool under most trying circumstances. I. COHEN.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—I thank your correspondent Mr. F. Mason for his invitation to state the reasons for the abandonment of the V engine in the design of the post-war Matchless, and, while I regret that my time is too fully occupied just now to allow of my entering into a lengthy correspondence on engine design, I will endeavour to give briefly the reasons for the change. It was, in short, to obtain greater refinement in running than can be secured with a V engine. The V engine possesses inherent defects in the lack of balance and unevenness of torque, which, although possible to minimise by careful design and workmanship, cannot be eliminated altogether. As regards power output, this is entirely independent of cylinder position, and there is no reason why a V engine should develop more power than a horizontal twin of the same capacity, or *vice versa*, assuming design in each to be equally correct. I may say that I do not regret my association with the V engine. It was developed during a period when speed, power, and reliability were, generally speaking, the only qualities that appealed to motor cyclists, and refinement of running would not have been appreciated had it been obtainable. The development of the sidecar machine, and the consequent gradual inclusion into the rank of motor cyclists of a class to whom this feature makes a greater appeal, has vastly increased its importance, and I am convinced that the future developments of motor cycle design will be in the direction of providing to a greater degree than before those qualities which can be described as refined running. In answer to your correspondent "A.M.I.E.E." in your issue of February 8th, the defects to which he refers regarding inaccessibility of the magneto, which exist in some horizontal twins, are not found in the model H Matchless, as any part of the magneto can be easily got at if necessary for cleaning or adjustments. I am pleased to note that your correspondent considers the design ahead of its foreign competitors. It has been the earnest endeavour of its designers to achieve that result, and to produce a machine that will regain for its manufacturers the position in the world's market that two years of non-production have lost.

Regarding handle-bar design, this to a great extent is a matter of opinion, but my own, supported by many years of riding experience of all types of machines, is that the long medium width bar as fitted is the best type for sidecar work, while the shorter and wider so-called semi-T.T. is preferable for solo work. Both types of bars will be available when the machine is marketed.

H. A. COLLIER.

LIGHTWEIGHT TRANSMISSION.

Sir,—In your issue of January 25th, Mr. R. Humphreys points out that the 1917 Diamond-Jap fulfils the ideals suggested on the 18th ult. by your contributor "H.M.B." for lightweight transmission, *i.e.*, chain-cum-belt with Enfield two-speed gear. May I point out another machine having this transmission—the Calthorpe-Jap?

For some two months last spring, previous to going to France, I was acting as assistant to a Division officer, R.E., in South Yorkshire. I purchased an early 1915 2½ h.p. model of this make, and found it an excellent mount for running about the countryside in the course of my work. On one occasion I had to make a journey from Doncaster to a village just west of Barnsley and back, as quickly as possible. The little machine made a top gear run there and back, except for a short stretch on one hill on which I was baulked, and averaged 23 m.p.h. without any pushing. The later models have variable ignition, which mine had not, so that climbing will be even better. My mount could do about 40 m.p.h. easily on the level, although I had no time to tune it.

May I congratulate you on the maintenance of the technical interest of your paper which first attracted me some five years ago—"knuttish" articles do not appeal, thanks! "Ixion" and "H.M.B." are two gentlemen to whom I am indebted for many pleasant articles and useful tips.

The "flat twin *v.* the rest" controversy is very interesting. Give me the flat twin for balance—experience will bring flexibility. May your spring frame campaign have the success it deserves *après la guerre*. I served my riding apprenticeship on an old 'bus with a modernised 80×80 Humber engine, fixed gear, and rigid forks—a most sporting old mount, but it taught me how to "nurse" an engine.

At present I am convalescent after a dose of trench fever, and only wish the doctor would allow me to get on to the open road. I must confess my own post-war ideas run more to a Morgan, a Williamson cycle car, or a Scott Sociable for company and comfort.

Another thing I think we shall look for on our bicycles will be throttle-controlled mechanical lubrication, fitted with a pressure "tell-tale" on the tank, as fitted to the dashes of many cars. Usual disclaimer. SAPPER SUB.

East Dulwich.

THE FLAT TWIN AT THE BAR.

Sir,—You have been very kind in publishing my letters on the subject of the "Flat Twin at the Bar." I did not intend writing any further on the matter, but I would just like to have one more word.

I entered this controversy simply owing to Mr. Bradshaw's condemnation of other types of engines except his own. I did not make any personal attack on him or his engine, but I, and many others to my knowledge, became very tired of his constant ridiculing of other people's ideas, and the threats of "rude shocks, etc.," which he was going to provide after the war. He had plenty of time to do this before the war.

Let Mr. Bradshaw make his engines any way he likes, but let him prove them on the track, and then talk if he is successful. It is not sportsmanlike to talk as he does now, when he knows there is no possibility of any racing, but his remarks will not be forgotten when racing is started.

I note with pleasure that Mr. Bradshaw has had a personal test of an M.A.G. engine, and I note his opinion is that it is nothing like as good as the A.B.C. That may be Mr. Bradshaw's idea, but I do not think it is others'.

With regard to the test in which Mr. Bradshaw wishes to put the M.A.G. engine up against one of his own, owing to the import restrictions I am not able to obtain one of the type which he requires, viz., our overhead inlet and exhaust valve racing engine—although I am trying to obtain one.

After the war our works will be able to produce a 45° V engine of perfect balance, but with more efficiency and better power, which the V twin always allows. From tests up to now this engine will run at 3,000 revolutions without being bolted down to a bed. These tests have been made on a 1,000 c.c. engine, and I hope it will prove a pleasant surprise to Mr. Bradshaw and many people who have so many times written in your columns to the effect that it is impossible to balance a V twin, especially a big one.

I read "A.M.I.E.E.'s" letter in a previous issue of your paper, and only wish to reply to this gentleman in consequence of the unfair remarks he makes regarding the manufacturers of the M.A.G. engines. I do, as he understands, represent the M.A.G., and am very proud of the fact that I represent such an excellent firm as are the manufacturers of this engine.

"A.M.I.E.E." cannot be commended for his broad-mindedness to start with, and he must surely realise that "One swallow does not make a summer." He states a firm in Schaffhausen, Switzerland, has delivered 300 motors for German submarines. It might be interesting to this gentleman to know—and I hope it will please him—that the M.A.G. manufacturers in Geneva are high up on the German black list. They manufacture munitions for the Italian, French, Russian, and British Governments. They make an enormous amount of munitions for France, thousands of automobile parts for transport waggons manufactured in this country, and in the next twelve months they have to manufacture a large number of 225 h.p. aero engines of a very renowned type for one of the Entente. They also have a factory in Turin, Italy, which, since the commencement of the war, has been occupied exclusively on munitions for the Italian Army and Navy.

This is all I have to say to "A.M.I.E.E.," who, I notice, was promptly dealt with by "Little John" in the last issue, which I was pleased to see, and I hope it will do him a little good.

I want to thank "Little John" for his kind words in the last issue. I did not intend mentioning the engine of which he writes, but I think it is an engine which will provide even Mr. Bradshaw with a gentle shock for revolutions, balance, power, and absence of heat. This engine has been tested after the finish of a six hours race by wax matches being laid on the tops of the cylinders and in the exhaust valves themselves, and they failed to ignite. This was a 3½ h.p. machine driven by Mr. Le Vack with a passenger in the sidecar. The cylinders were highly polished, and there was no sign of colour on either. It finished third after interminable tyre trouble.

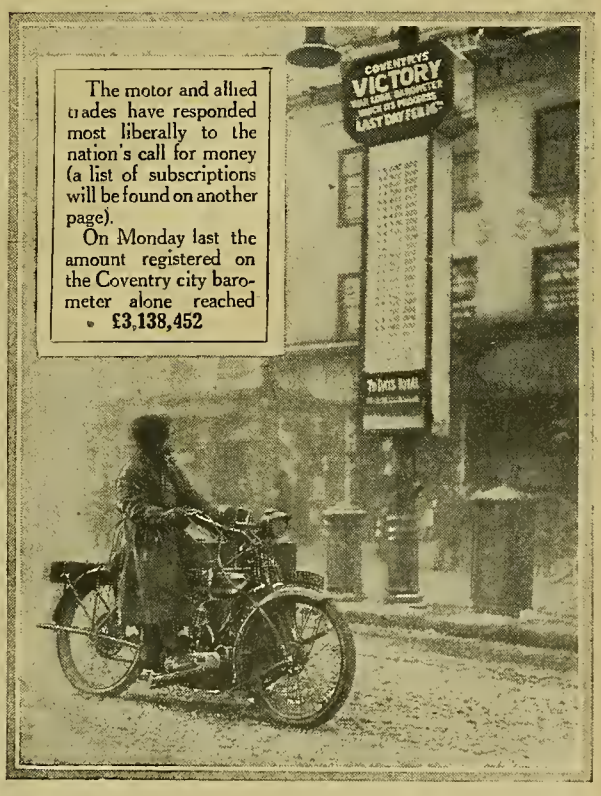
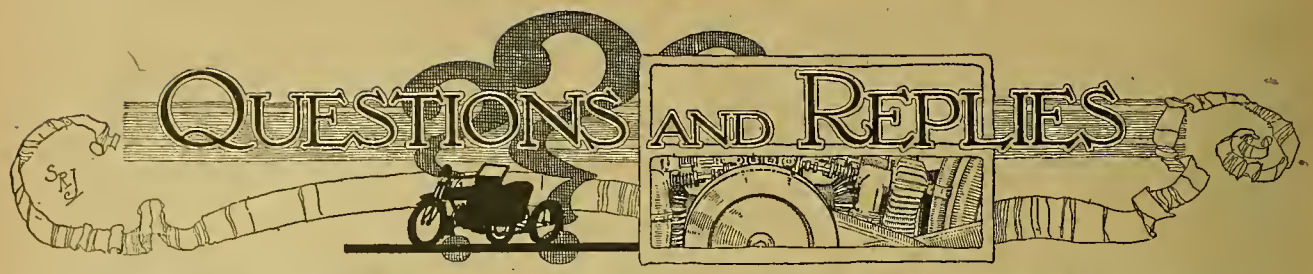
THE VICTORY LOAN.



The motor and allied trades have responded most liberally to the nation's call for money (a list of subscriptions will be found on another page).
On Monday last the amount registered on the Coventry city barometer alone reached
£3,138,452
COVENTRY'S
VICTORY
LAST DAY FOR LIST



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Obstructed Petrol Feed.

My machine when started up will go perfectly for about fifty yards, but then suddenly slows down, though it will run fairly well if I close the air. If, however, I open the air again, it will immediately slow down and stop. I lately cleaned out the carburetter, and I think the platinum points are clean. —A.C.

There is probably some foreign matter in the carburetter or jet, as the symptoms lead one to think that the petrol flow is obstructed in some way. Of course, it is possible that the obstruction may be in the petrol pipe or tank.

Using Heavy Fuels.

I shall be greatly obliged if you will give me a little information regarding the use of petrol substitute. I ride a 2¼ h.p. Triumph, and as I am unable to obtain enough petrol to run it as often as I require, I have been considering the advisability of using petrol substitute. I have little or no knowledge regarding the effect on the engine of using any spirit other than petrol, and what I want to know is, would there be any likelihood of my having trouble with the engine if I were to use any of the substitutes sold?—S.A.

A mixture of half petrol and half substitute should not harm your engine. If you use a heavier mixture than this you will have difficulty in starting; indeed, we think that the amount of heavy fuel you can use will be decided by the mixture on which the engine will start. On frosty mornings, after the machine has stood over night, you may find it very difficult to get the engine to fire on the half-and-half mixture, but boiling water poured over the induction pipe will invariably enable an easy start to be made. Ordinarily, an injection of petrol should suffice, and it is a good plan to allow the engine to drain the carburetter when the machine is put away over night. If the fuel is allowed to stand in the carburetter for any length of time the lighter spirits evaporate, leaving only the heavy oils, so that the carburetter contains a very heavy mixture when next an attempt to start is made. Use slightly more oil than hitherto, and fit a hot air intake to the carburetter. We consider the use of heavy fuels at any time dangerous unless this be done. Also the crank case should be sheltered from cold air so far as is possible, the silencer of the baby Triumph answering a useful purpose in this direction.

Stopping a Blow Hole.

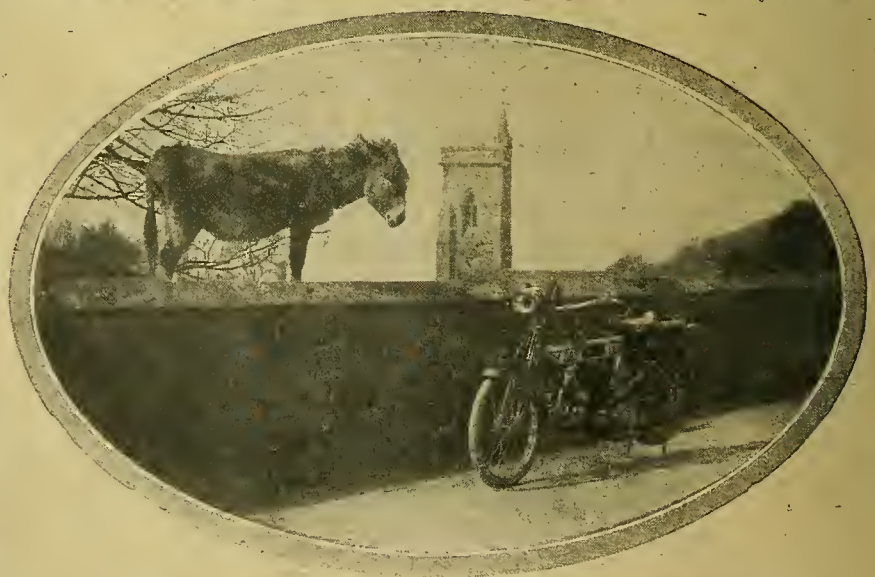
My Scott motor cycle when laid aside some months ago was running well. When trying it recently it was sluggish and uncertain, and I only ran it a few hundred yards, as I intended to clean the cylinders. On proceeding to do this, I found a hole in the bottom of the right-hand crank case chamber, through which all oil had escaped. The hole was small, and looked as if the sharp end of a file had been driven through it. I should like to know how this happened, but I am more anxious to find out how I can repair it. As you know, this is a most awkward place to execute repairs, the space is so narrow. Would any of the following be of use? The metal is aluminium. (1.) Pouring molten lead into the crank case. (2.) A short bolt with a large head and leather washer pushed from above downwards, and secured with another leather washer and nut.—W.W.

Possibly the damage was due to a flaw in the casting which has just developed. The hole could be repaired by acetylene welding quite easily, or it might be enlarged, tapped, and a brass plug screwed in. Pouring in molten lead would be of no help to you. The bolt idea, however, is quite good.

Poor Compression in Front Cylinder.

I have a 1915 7-9 h.p. twin Indian combination. My trouble is that I cannot get good compression in the front cylinder. In July I had the misfortune to score the front cylinder a little owing to the piston rings getting stuck. The local agent fitted a new cylinder and also step rings, which he thought would be best. Since then the machine has done about 250 miles, yet the compression is still very poor in the front cylinder. The machine is otherwise in perfect condition, having only done 3,800 miles.—A.L.

Loss of compression on the front cylinder of a twin-cylinder machine is a very common fault; it is usually caused through lack of lubrication. If the valves are carefully ground in, and the washer beneath the inlet valve seating is in good order and not allowing compression to escape, and you are sure the piston rings are a good fit, the only other cause on your particular make of machine is insufficient oil. You should then adjust your mechanical oil pump so as to direct all oil to the front cylinder; this is done by screwing down the little needle valve situated at the oil pipe junction on the timing case. Also make sure the pump is working properly. Remove small screw at the pump base to relieve any air locks.



["....."] A copy of the new edition of "Motor Cycles and How to Manage Them" will be presented for the best title submitted for the above picture before the end of the month.

Using an N.S.U. Gear.

Will you kindly tell me the correct way to change gear on the N.S.U. gear? (1.) Is it necessary to close the throttle entirely when changing or only to close it a little, as in this gear the clutch has to be withdrawn every time? (2.) Does it damage the gear to change down quickly, as if this is not done the machine loses way on a steep hill?—V.Q.

(1.) With this gear all that is necessary when changing is to prevent the engine racing; closing the throttle slightly is all that is needed. (2.) You cannot well damage the gear by changing down quickly; in fact, provided the machine is not travelling too fast, the quicker the change is made the better.

Soldering a Tank.

Would you kindly suggest a means of soldering a motor cycle tank? I have tried twice or three times with ordinary soldering materials after thoroughly cleaning the part, but the petrol still creeps through after a little time.—F.C.C.

See that all the surfaces to be joined up are bright and clean. Then dress the part with a good soldering flux and use a hot copper-ended iron, which must be properly tinned. This is done by cleaning till bright, heating, and dipping in flux, and the point is rubbed well with solder on a clean piece of tin till evenly coated with a thin plating. You will, of course, see that there is no trace of petrol in the tank before attempting the repair. If the leak is anything but a simple one you would be well advised to send the repair to a tank maker. A blow lamp may be necessary, but its use is very dangerous except in accustomed hands, owing to the likelihood of explosion in the tank.

Butt Ended Troubles.

My machine is a 3½ h.p. single-cylinder combination. Last spring, requiring a new tube for the driving wheel of the motor cycle, for convenience of repairs, I had a "butt end" put in, which cost then about 9s., but unfortunately it went wrong very quickly inside the butt. It was repaired by the makers, but went in the same way soon after; and I have had three others since—all gone in the same place, viz., inside the butt. I had them repaired, and put round the rim a thick lining of tape, thinking that probably a spoke head had caused the trouble; but to no purpose. I can blow the tubes up quite hard out of the cover, but they will not last long when fitted. Will you please give me your advice?—F.A.

Faulty fittings, butts not pushed firmly home, grit or dust between butts, dirt or grit in the cover, or creeping cover, are the chief cause of troubles such as you have experienced. Use plenty of French chalk on the joint when fitting ends together. Possibly the use of security bolts would improve things, but if fitted carefully the tubes should cause no trouble, as illustrated by the fact that many leading competition riders used to employ this type.

READERS' REPLIES.

Again—Which Wheel Lifts?

In reference to your reply to "F.C.B." in your last issue, you may be interested to hear that in June last, while I was a passenger in a Montgomery coachbuilt sidecar attached to a 1914 4 h.p. Triumph, the driver took a *right*-hand turn too fast, with the result that the whole outfit rose on to the sidecar wheel, which, being unable to stand the strain, buckled up, throwing me into the road. The outfit finished up lying on the near side of the sidecar. I had three very enjoyable weeks in hospital as a result of the accident, but the driver got off without a scratch, and the outfit sustained no further damage than a buckled wheel.—F. A. Hudson, Bombdr. R.F.A. (formerly H.S., M.G.C.)

Refusal to Fire on Front Cylinder.

In the issue of February 1st of the "good old blue 'un" a letter in "Questions and Replies," signed "A.H.L.," interests me, because I have had similar trouble with a Douglas, *i.e.*, erratic firing in the front cylinder. I tried *everything* your answer to him suggests, but it was of no avail. I even took the engine down, cleaned the pistons, cylinder heads, valves—everything I could think of. At last in desperation I took off the magneto and sent it to the makers for overhaul, and a partially broken down armature winding proved to be the cause of the trouble. The Douglas in question runs perfectly now.—M. W. Fyfield.

Tuning a Scott.

In *The Motor Cycle* for January 25th "T.J.D." is asking for hints *re* the Scott motor cycle. Regarding lubrication, you advise him to keep the plunger of the lubricator clipped down. If he uses this method I would advise him to make sure the machine is getting oil. If the pump washer is a tight fit, and there is the slightest air leak in the feed pipes or nipples, the machine will not get oil. If he desires to be quite sure regarding oiling, he should adopt the method described in *The Motor Cycle*, December 16th, 1915. For other hints you advise him to read the number for September 14th, 1916. I think he would get better information in the issues for July 15th and 22nd, 1915.

On February 1st "G.G." is also enquiring *re* the Scott, complaining of heavy consumption, low power, and low speed. All these may be caused by three maladjustments (I assume he has a Scott carburetter fitted): (1) Jet too large, (2) petrol level too high, and (3) magneto timing too slow. The remedy for No. 1 is fit a smaller jet or run with jet chamber cover partially or fully open. (2.) The level should be $\frac{7}{16}$in. or $\frac{1}{2}$in. below top of jet. Adjust needle spring until the float (with carburetter empty) just lifts the needle valve. (3.) The correct method of timing is as follows: Remove plugs, retard spark lever, put the bell crank lever on centre of rear segment, put the high gear in, revolve engine backwards by means of rear wheel until near side piston is just descending, and couple up.

I would strongly advise both correspondents, if they are using Scott carburetters, to fit an adjustable jet, when they will get better consumption and easier starting.—Jas. Thompson.

I wonder if "G.G." has detached the silencer drain pipe from the small silencer and thoroughly cleaned the holes in the drain pipe. Some Scott riders seem to think it is sufficient if they clean out the holes at the end of the small silencer, but to ensure good running the drain pipe must be disconnected from the small silencer every few hundred miles, and the drain pipe holes which open into the small silencer thoroughly cleaned; this is quite an easy job. With regard to petrol consumption, I have a 1915 Scott and sidecar, and when running with my wife, boy, and luggage—about twenty-four stone in all—I do not have any difficulty in doing upwards of 55 m.p.g. I have frequently checked this when touring in hilly country in Wales and Devonshire. With regard to "G.G.'s" third query as to the Scott machine being suitable for long journeys with a sidecar, I should like to say that I have found the Scott eminently suitable for work of this character. I have been several lengthy tours averaging over 100 miles per day, and have never had the slightest trouble, although I was perfectly ignorant of all things relating to motor cycling when I bought a Scott combination in 1915. The only hill on which I have failed to make a clean ascent with full complement of passengers has been the hill from Lynmouth to Lynton, and for this reason I think it would be an advantage if the Scott Co. would provide a low third emergency gear, which would be useful for crawling round the hairpin bends on such hills as Lynton.—H.E.G.

I observe in your valuable paper a question by "G.G." on tuning a 1914 Scott. I am the owner of a 3¾ h.p. 1914 Scott, with Scott carburetter fitted. Some time ago this machine developed the same trouble as stated in "G.G.'s" letter—no power on hills, excessive petrol consumption—but in this case it was very difficult to start. Several mechanics were heat to "cure" it, and as a last resource (being a mechanic myself) I tried a slightly stronger spring in the air valve of the carburetter. The result was I can start the engine from cold on top gear at walking pace, I have plenty of power on hills, and petrol consumption is 75 m.p.g. solo. It is an advantage, especially when using heavy fuel, to fit only one gauze of slightly wider mesh to each transfer port, and the fitting of Reliance plugs greatly helps the regular running of a Scott.—SD 2422.

RECOMMENDED ROUTES.

Coventry to Oldham.—J.T.

Coventry, Stonebridge, Coleshill, Weeford, Lichfield, Armitage, Rugeley, Stone, Newcastle, Red Bull, Congleton, Alderley, Wilmslow, Cheadle, Stockport, Hyde, Ashton, Oldham.

Shifnal to Reigate.—K.C.S.

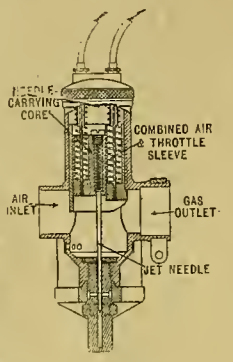
Shifnal, Bridgnorth, Kidderminster, Bromsgrove, Headless Cross, Alcester, Stratford-on-Avon, Shipston-on-Stour, Enstone, Woodstock, Oxford, Dorchester, Henley, Maidenhead, Windsor, Staines, Chertsey, Weybridge, Cobham, Leatherhead, Dorking, Reigate. Approximately 178 miles.

PATENTS

BY ERIC W WALFORD.

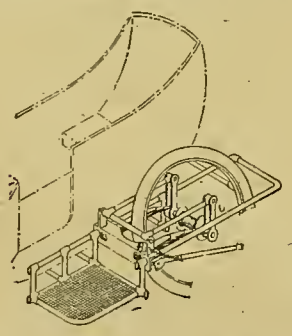
A Novel Carburetter.

This is a two-lever carburetter in which the levers, instead of operating a throttle and an extra air valve as usual, actuate (1) a combined air and throttle member, and (2) a needle whereby the jet opening is varied. The carburetter body is on the usual lines, and encloses a cylindrical sleeve, which on the inlet side controls the air going in, and on the opposite side regulates the gas passing out, the sleeve being cut away at its lower end to produce the required effect. Within the sleeve is a sliding core. This core is drilled centrally from the top to receive the jet-controlling needle, and the needle is pressed down by a spring retained in position by a screw cap. The taper of the needle is designed to give a gradually variable jet outlet, and the core carrying the needle is actuated by a Bowden wire. The air and gas control sleeve is similarly operated, and in combination the two means of control enable a wide variation in results to be obtained.—R. C. Davis, No. 16,755, 1915.



Sidecar Wheel Springing.

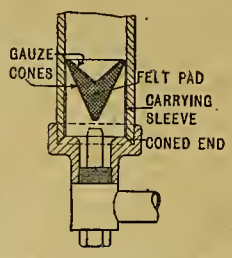
The perspective view shows clearly how the sidecar wheel spindle is supported at the ends of a pair of semi-cantilever springs. One spring is arranged at each side, and the spring ends are formed with eyes, in which the wheel spindle is secured. To prevent tilting of the wheel there is employed a rigid fork member, which is pivoted just above the



spring mountings, and the ends of this fork member are connected with the wheel spindle on either side by a pair of links. The construction forms a substantial spring mounting for the sidecar wheel, and the attachment member for the springs affords a convenient medium for the attachment of a footboard.—G. E. Rigby, No. 102,165.

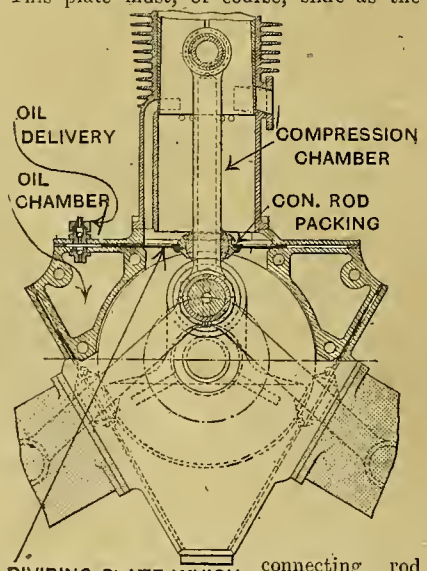
Improving the Mixture.

In order thoroughly to mix the petrol and air passing through the carburetter, there is arranged just above the jet nozzle a device which comprises a pad of felt or similar absorbent material confined between a pair of dished washers of gauze. The conical member thus formed is attached to a sleeve, which is coned at its lower end and secured in position by being gripped between the parts indicated. Thus the mixture is compelled to pass through the felt, with the result that an intimate mixture is produced.—F. Newton and J. Howarth, No. 17,011, 1915.



A Two-stroke Radial Engine.

It will be seen that in this engine there are three cylinders mounted upon a triangular crank chamber. The crank chamber and cylinders may be stationary, in which case the crankshaft will rotate in the usual manner, or the crankshaft may be fixed and the cylinders rotate. In the present engine the two-stroke cycle is employed, the initial compression of the gas taking place in the lower part of the cylinders. The lower end of each cylinder is cut off from the crank chamber by a sliding plate, which is formed with a universal packing through which the connecting rod passes. This plate must, of course, slide as the



connecting rod moves, and an important feature of the present patent is that the sliding of this plate is employed for the purpose of supplying lubricant under pressure. The lubricating oil is contained in compartments at the corners of the crank case, and there are arranged at the desired points inlet and outlet valves, which are shown as ball valves in the drawing. Movement of the dividing plate first sucks oil from the oil chamber, and then forces it through the ball valve to the supply pipe.—E. T. W. Addyman, No. 8,110, 1915.

SPARKLETS

Extra Postage.

The Stanley Motor Belt and Fastener Co. point out that motor cyclists ordering the box of Stanley spares by post should state the belt size, and add 2d. for extra postage.

Motor Cycle Supply.

We are informed by the Wulfruna Engineering Co., Ltd., Great Brickkiln Street, Birmingham, that they are in a position to supply motor cycles to the British public up to March 15th.

Bowden Replacements.

Being wholly engaged upon production for the British and Allied Governments, the Bowden Wire, Ltd., are unable to execute any orders for private purposes until further notice, but they have in stock certain goods suitable for replacements. Customers are invited to state their requirements in this respect, and, if possible, these will be met.

N.S.U. Gears.

For many years Messrs. Eagles and Co., 275, High Street, Acton, London, W., have specialised in the repair of N.S.U. gears. They will be happy to send to any reader of *The Motor Cycle* a pamphlet giving full particulars of the British-made N.S.U. gear, together with a sectional illustration, and an illustrated price list containing the numbered spare parts. All repairs to these gears, including the earliest types, can be executed within a few days.

J.A.P. Catalogue.

A new descriptive booklet referring to the 6 h.p. and 8 h.p. twin-cylinder J.A.P. engines is now available. Both engines are illustrated by carefully prepared sectional diagrams, and a perusal of the brochure should suffice to give any motor cyclist a thorough insight into the features of these two popular types. Besides this, the catalogue contains many hints and tips of value both to the expert and novice. A copy will be sent post free on application to Messrs. J. A. Prestwich and Co., of Tottenham, London, N.

B.S.A. Catalogue.

The reproductions in the 1917 edition of the B.S.A. motor cycle catalogue are effectively displayed in colour, and the specifications clearly and concisely given of both the 3½ h.p. and 4¼ h.p. machines. The list will be forwarded free on application to B.S.A. Co., Ltd., Birmingham.

Excelsior Catalogue.

We are in receipt of the latest catalogue of Messrs. Bayliss, Thomas and Co., Coventry, makers of the British Excelsior motor cycle. All models except the latest 4 h.p. twin are illustrated, but at present it is not known how many of the models it will be possible to make deliveries of, as it cannot yet be seen what effect the new manufacturing restriction Order will have.

WHITELEYS

WILL SUPPLY YOU WITH

ANY MAKE OF MOTOR CYCLE BY EASY PAYMENTS.

Delivery on Payment of £5 to £10 Deposit.

2% only added to List Prices for a year's credit.

Should you select a **CALTHORPE J.** two-speed (cash price, 38 guineas) you pay 16/- extra only. The machine is delivered after payment of **£8,** to be followed by 12 monthly payments of **£2 14s. 6d.**

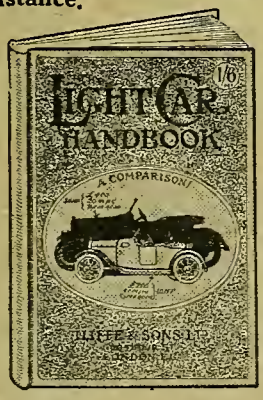
Wm. WHITELEY, Ltd., QUEEN'S ROAD, LONDON, W.

This is undoubtedly a book which will be found of the greatest service to every man or woman who owns, or is thinking of buying a light car, and wishes to drive and look after it without assistance.



Price 1/6 net. Post paid, home or abroad, 1/9.

Obtainable from the Publishers,

ILIFFE & SONS LIMITED, 20, Tudor St., London, E.C.

and all leading booksellers and bookstalls.

The LIGHT CAR HANDBOOK

(issued in conjunction with "The Light Car") is intended to assist owners and drivers of light cars to get a better understanding of the mechanism of the vehicles they use, and to give useful information and advice in respect to care and management. It is written by a private motorist who has had actual road experience with many different makes of light cars and who understands, therefore, exactly what the amateur motorist wants to know about the car he drives. The language is plain and concise.

The opening chapters deal with the economy of the light car, its usefulness and possibilities. Helpful advice is given on the choice of a car, and its equipment. The following chapters deal with chassis and engine construction and explain the working of the power and other units. Each important item of the car—the carburetter, magneto, lighting dynamos, cooling and lubricating systems, engine starters, gear box, axles, springs, brakes, wheels and tyres—is treated in a separate chapter and numerous illustrations are included to supplement the descriptions. The final chapters are devoted to coachwork, accessories, driving, garaging the car, and the law as it affects motorists.

List of Contents.

Chap.
I.—The Charm of the Light Car.
II.—The Choice of a Light Car.
III.—The Expenses of a Light Car.
IV.—A Typical Chassis.
V.—How the Engine Works.
VI.—Engine Design.
VII.—The Carburetter.
VIII.—The Ignition.
IX.—Engine Lubrication.
X.—The Engine Cooling System.
XI.—The Clutch.
XII.—The Change Speed Gear.
XIII.—Universal Joints and Back Axles.
XIV.—Front Axles & Steering Gears.
XV.—Frames, Springs, and Brakes.
XVI.—Tyres and Wheels.
XVII.—Coachwork.
XVIII.—Accessories.
XIX.—Lighting Dynamos and Engine Starters.
XX.—How to Start the Engine.
XXI.—How to Change Gear.
XXII.—The First Drive and Expert Driving.
XXIII.—The Car in its Garage.
XXIV.—The Owner and the Law.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed ——— & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

A WAR LOAN MOTOR BIKE?

IT would be a great convenience to you in your business to have a motor cycle, and you have the cash ready for its purchase! Yet you feel that all your available cash should be put into the War Loan.

IF this is your difficulty, perhaps GODFREY'S can assist you, as they can supply you with just the motor cycle or combination you require, and you can pay for it—

Not in Cash, but in War Loan Stock

a happy combination of patriotism and business being the result.

IN the case of second-hand machines purchased in this manner, GODFREY'S will allow **a special discount of 5%.**

IF you wish to keep your War Loan you merely deposit the stock as security, and pay for the machine in 12 equal monthly instalments. GODFREY'S will not charge you any interest, whilst YOU will be receiving interest from your investment, and on the final instalment being paid your War Loan Stock will be handed back to you.

Payments by War Loan Stock will be accepted for all, or any, purchase made during the month of February.

Write for our full and complete Lists of New and Second-hand Motor Cycles and Light Cars, and send particulars of any machine you may have to offer in part exchange.

GODFREY'S LTD.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

Tottenham Court Road,
London, W.C.

Dear Sirs,—I have just been reading my "Motor Cycle" of this week's date, Jan. 4th, and was struck with your advertisement, and the many excellent testimonials which you have received from various people. On considering the matter, I must say that I can endorse the opinions mentioned in every way, and even would go further, and say that for courtesy, quickness of despatch, and business-like methods generally, I shall always recommend Taylors.

Yours faithfully,

A Satisfied Customer writes:

29th January, 1917.

Messrs. H. Taylor & Co., Ltd.,
London.

Dear Sirs,—I beg to thank you for sending the Renold chain so promptly, which came to hand on Saturday. I may mention that I tried not less than a dozen places before noticing that you dealt in "parts"; and I had practically given up hopes. Some firms did not take the trouble to reply, including one man who advertises weekly that he has all kinds of driving chains in stock for immediate delivery, **and I wrote him twice.** I also thank you for the Catalogue, and I shall know where to apply to when next requiring anything. Yours faithfully, J. L. D.

1915 3½h.p. 3-speed Sunbeam Combination, fully equipped, excellent condition; £80; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0862

Not merely a Fancy Pattern.

THE Beldam Tyre is not merely a fancy pattern—it is designed on scientific principles. As a result it does not cut easily. It has most rubber where liability to puncture is greatest. It is narrow and crisp and has a side grip which makes "cornering" safe and comfortable. Apart from these advantages Beldam Motor Cycle Tyres last long.

The Beldam Tyre Co., Limited, Brentford, Middlesex.

New Zealand: J. E. Fitzgerald, 139, Lambton Quay, Wellington, Cape Colony: The Tyre and Motor Co., Rodney St., Port Elizabeth. India: Wilkinson & Co., 12, Dalhousie St., E., Calcutta. Ireland: P. Drohan & Sons, Carrick-on-Suir.

Retreads The Plant, Materials, and Men behind BELDAM RETREADS are the same as employed in making the famous Beldam Tyres—Quality is the note all through. Have your old Tyres retreaded in the Beldam way before they get beyond repair. Estimate of cost by return post.—The Beldam Tyre Co., Limited, Brentford, Middlesex.

Godbolds

MOTOR CYCLES FOR SALE.

Sunbeam.

SUNBEAM, 1916, 3½h.p., speedometer, lamps, horn, just overhauled by makers, perfect; £75.—W. and H. Motor Co., Ltd., 287, Deansgate, Manchester. [8075

Motor Drivers in the Infantry.

THE demand for general service men in the combatant sections of the Army is such that hundreds of men who enlisted in the Motor Transport service of the Army Service Corps are being transferred to infantry battalions. Such is the information conveyed in letters to us on the subject, in which the writers express surprise, since the majority of them had previously been trade tested and approved, and consider that as motor drivers and mechanics they would be rendering better service to their country than in taking their places in the firing line. We are not clear at the moment whether the transfer applies only to single men —several readers who are affected are not precise on this point—or even to recent recruits, but it is a well known fact that much dissatisfaction has existed for a long time past that young able-bodied single men should be retained in "safe" jobs, when thousands of married men with family responsibilities are fighting with the bayonet. We believe that the combing out does not apply solely to the M.T., but whatever change is in process we can only urge that the Government's action must be dictated by the exigencies of the situation, and no patriot will need any further assurance than that. Such is the feeling of the country that the War Cabinet will have unanimous support in any action they may take to find sufficient reserves to maintain our combatant forces at full strength. Evidently sufficient technical men are now available for the Transport sections, for the original mistake of enlisting engineers in the infantry at the start of the war, and subsequently having to withdraw them after training, is too fresh in one's memory to admit of the likelihood of repetition.

This supposition is confirmed by the refusal of certain non-combatant units to accept young men of A category, who were until recently engaged on munition work, but are now debadged. The apparent rule is hard on youths in the engineering profession who had hoped to be able to continue in the M.T. or R.F.C., for instance, work which had attracted them originally. Though they have been engaged on war work for a long time past, they apparently are left with a limited choice of section.

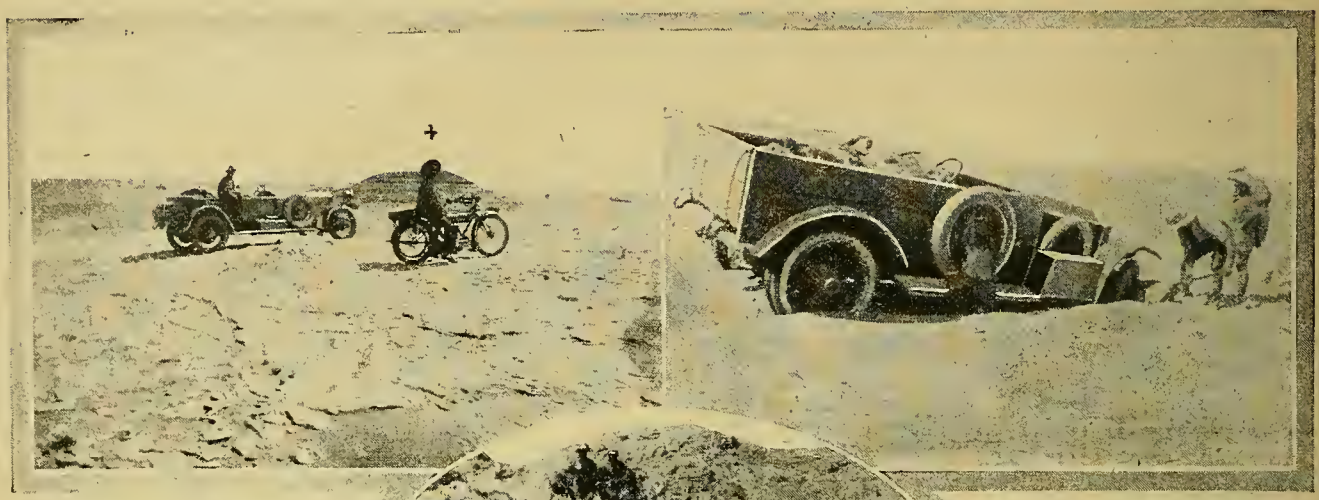
More Government Motor Cycles.

WE have on former occasions referred to the national work which the motor cycle industry has been able to render in this time of stress. As the hands were accustomed to working to the finest tolerances in peace time in the production of motor cycles, these factories were at once available for the production of important munitions. But apart from munitions as such, the staple trade of the factories—*i.e.*, the motor cycles which emerged therefrom in their hundreds in happier times—was found to have attained a degree of reliability and usefulness which rendered the machines absolutely indispensable as despatch carriers and connecting links between different headquarters and the army in the field. Derided in peace time the motor cyclist and his machine to-day are probably the most popular unit in the British Army. So far from the requirements of British and Allied armies having been satisfied by the different factories in the matter of motor cycles, it is pleasing to be able to record that at this moment a number of new factories have been pressed into the services of the Government, and are now busily engaged in the production of hundreds of new motor cycles. The Russian Government order, to which we have referred on several occasions in the past, has now been distributed among British firms, and it is refreshing to those who have worked hard in the perfection of the motor cycle for years past to know that the use of such machines is being extended right and left, and that they have long since been regarded as an inseparable part of a modern army.

An index to the advertisements in this issue will be found on the page facing the back cover.

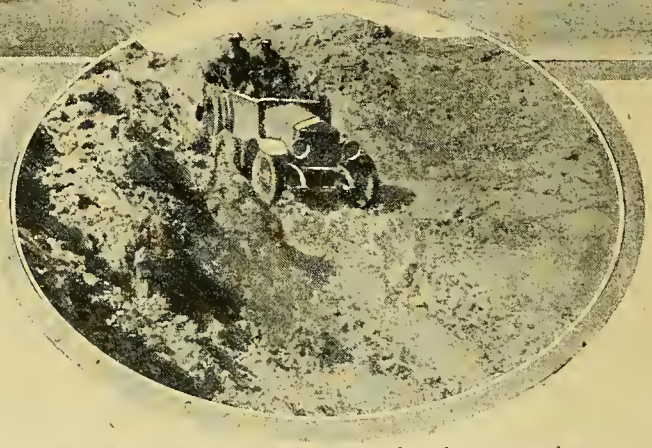
CHASING THE SENUSSI.

A Motor Cyclist with an Armoured Car Section operating on the Libyan Desert.



(1) A Rolls-Royce and a Triumph near the Boharia Oasis.

(2) A transport car in difficulties. This photograph conveys some idea of the appalling difficulties of transit encountered in Egypt.



(3) A "road" which is more reminiscent of a volcano crater than a highway.

THE following account of life in the Egyptian desert has been received from Cpl. L. Godsell, a despatch rider operating with an armoured car section. He reminds us that the majority of the men with the Rolls-Royce cars and motor cycles which he speaks of were recruited by *The Motor Cycle* for the Motor Machine Gun Service many months ago, and have much active service to their credit. Everyone has heard tales of the adventures with the Senussi—a tribe or sect of the Eastern Sahara which was many years ago organised with the aim of securing political independence of the Moslem world, and which, though not actually dangerous, has proved extremely troublesome. This is Cpl. Godsell's letter to the Editor:

Through Sand for 200 Miles.

"Most of the boys here were recruited by you and are in the best of health. One of the photographs is of myself on my motor cycle and of a Rolls-Royce car near the Boharia Oasis, which, as you will have seen by the papers, is now in the hands of the British. Two months before our occupation two officers had ventured out to reconnoitre this district, but never returned. They were captured by the Senussi. This outlandish place is most difficult of access, the surface being very hard rock. After we had done about 200 miles of soft desert sand we had to face ten miles of this appalling surface. Keeping pace with the Rolls was no joke, and the hard sharp rock was bad for the tyres, but the old Coventry bicycle behaved finely. Several times we had to put the machine on the Rolls box waggon to save the tyres for the return journey. A few days after this journey the oasis was taken by our troops, and afterwards we left that part for Dakhl. No. 2 shows the Rolls held up by a sand dune. Some of these dunes are 20ft. high, and are comparatively easy to get over, as the sand is crusted on top, but to do so they have to be taken at a good speed. When striking a dune the driver slips out the clutch, which prevents shock to the transmission. If the car does not successfully mount the rise, it dives in, and has to be got out for another try. We have travelled up and down the dunes for twenty miles without a stick. Then we get level plains from five to twenty miles long, with an occasional break of a few miles of hilly and very rough going, a strenuous test for the machines.

Since the accompanying notes arrived from Cpl. L. Godsell, news has been received that the operations against the main forces of Sayed Ahmed, the Senussi leader in the Western Desert, have just been brought to a successful conclusion.

It will be recollected that early last year the Senussi Sheik attempted to invade Egypt but was driven from the whole of the coast region of Western Egypt by the operations which ended in the re-occupation of Sollum. By the end of last year Kharga, Fanfara, Dakhl and Boharia oases had been cleared of the enemy, only Siwa and Jarakuts of Egyptian territory remaining in their hands. Kufra, in the Libyan Desert, is the permanent headquarters of the Senussi, and is 350 miles distant from Siwa.

A Rise of 1 in 3.

"One of the pictures will give you some idea of the rough ground over which we have to travel. The machines are on the cars in this case, as this was our return. On the way out we rode the cycles up this atrocious cliff, which is about 1 in 3. I hope you will be able to use some of these pictures for your paper, as they may be of interest to many of your readers. I get *The Motor Cycle* most weeks sent out by my friends, and I pass many an hour with it. I have just returned from a 300 mile run with Triumph bicycles and Rolls-Royce cars, and had a good run and very good luck, mostly plains where we could open out. It is hard for bicycles to keep up with the cars, but they stick it splendidly. The only trouble I had was an exhaust valve burn out. I noticed a writer in your journal a few weeks ago stated a 4 h.p. Triumph was never known to overheat or konk out. I have to ease my machine very often. It heats up in this country, and I do not know what engine would not do so, going 'all out' for ten to twenty miles at a stretch over such appalling tracts."

OCCASIONAL COMMENTS

BY "IXION"

"Drying Up."

EVERY now and then a passing allusion in our correspondence columns shows that the average rider is still as ignorant of the phenomenon vulgarly known as "drying up" as experts are bemused as to its precise significance. "Little John," to quote the latest example, calmly ascribes the tiring of his Douglas after a mile of speed to its possession of a flat twin engine, in sublime ignorance of the fact that practically any motor cycle engine will tire after a mile of full throttle under certain conditions. Let me quote two parallel examples. Exactly eleven years ago I bought a new Triumph motor bicycle which on first acquaintance intoxicated me, being a huge advance on the 1905 model. But the first time I took it out on a club scrap I made the disquieting discovery that it would "overheat" on the level. "Overheating" on hills was our universal experience in those days, but I had never before met an engine which would konk its heart out on the flat; and judge of my mortification after mopping up our entire membership on the homeward run, I ignominously dismounted on a hill consisting of 500 yards of 1 in 15 or thereabouts! In 1914 I was driving a water-cooled four-cylinder light car out of Tavistock towards Exeter, when it suddenly converted itself into a traction engine, and produced huge clouds of white steam.

Heat the Prime Cause.

IN both cases, heat was obviously the prime cause, as also in the "drying up" of "Little John's" Douglas. The Triumph experts, consulted in the first case, took out a deep-slotted exhaust valve, and fitted me another with a perfectly smooth head. The new valve effected no perceptible improvement, and I drove that machine very gingerly for three months until I met two strangers with similar mounts, both amateurs, each of whom vowed that his favourite plug (each a different make) was the only cure. I took the hint, got a dozen assorted plugs, and found that the engine always dried up with certain plugs, and never with others. The sole trouble was that the electrodes of badly designed plugs became incandescent after being submitted to a high temperature for a given time. In extreme cases, apparently, the electrodes reached such a temperature that ignition occurred too early for the highest possible speed on the level; with less atrocious plugs, one presumes, the firing point was delayed a trifle, and pre-ignition only became apparent when the engine was slowed down for a hill. There is a third, and more mysterious, trouble associated with the same causes; but this we will not name for the moment. These and similar memories returned to mind when the light cars of 1914 followed the example of the 1907 bicycles, and once again a change of plug produced an instantaneous cure. In all probability, "Little John's" Douglas would have lasted ten laps of Brooklands all out if he had simply changed his plugs.

"Silent Discharge."

IN common with many of our readers, I was very disappointed that the electrical experts showed so little interest when a contributor to *The Motor Cycle* suggested that under certain conditions, sometimes found in combination with a very hot engine, an electric current may leap the sparking plug gap without producing any spark at all. The idea was new to most of us, and may be fallacious. But any motorist who can boast a varied experience of hot engines, ranging from the first super-efficient 3½ h.p. bicycles to the 1914 light cars and the 1916 two-strokes, knows that some heat stoppages, alike on the level and uphill, are devoid of the normal symptoms of pre-ignition. The engine calmly peters out without any shock or noise, it silently dies away, and probably restarts quite obediently in a minute or two. That this phenomenon is produced by heat is undeniable. But the definition of the secondary cause is elusive. In the old days we used to suppose that the piston and cylinder, and maybe the valves, had undergone some fierce spasm of distortion, and that the compression had momentarily ceased to serve for a useful power stroke. Quite recently I have heard men guess that the sparking plug points expanded under the fierce heat till they met and shorted! The first of these speculations is absurd, and the second is not at all plausible. In the meantime the subject has surely received enough prominence by now for our newest and youngest readers to understand that "drying up" is almost universally ascribable to bad sparking plugs, or, in some cases, to the overheating of a second-class plug by some temporary defect in the engine, such as shortage of oil or insufficient exhaust tappet clearance.

Another Use of Graphite.

IN my experiments with graphite I have hit on one use of it which strikes me as really valuable. If you are troubled with piston rings gumming in their grooves, try putting a little graphite in the groove next time you fit a new ring. I am not going to say it is a certain remedy with baby two-strokes, some of which can practically weld up their top ring solid with the piston in a thousand miles, so that you have to chip it out by instalments with a cold chisel. But it retards the process even in these extreme cases, and seems to ensure the freeness of the rings in specially oily cylinders on four-stroke engines. Graphite is notoriously more resistant to heat than any other lubricant, and some enthusiasts state that it renders all carbon deposits much softer and easier to dislodge. However that may be, I am very pleased with the properties it displays in keeping the piston rings free in their grooves. I have not tried graphite grease for the purpose named, but employed Oildag, thinned with a *very* little cylinder oil, and brushed well into the grooves; if much oil is used, the tip will defeat its own object.

OVERHAULING AN ENGINE-SHAFT GEAR.

Instructions and Hints on Dismantling and Overhauling an N.S.U. Gear.

THE N.S.U. engine-shaft epicyclic two-speed gear was fitted to various makes of machines. Though of German origin, it is certainly a wonderfully efficient and neat means of obtaining a variable gear. The fact that it is to be found on numbers of motor cycles other than the N.S.U. is probably because it is one of the simplest gears to fit to a machine having a direct belt drive, and the ease with which it can be attached and detached renders it most useful to the rider who on many occasions prefers to use his machine as a simple single speeder, though occasionally a ride has to be undertaken which necessitates a variable gear.

Few riders seem to understand the construction or how to tackle the few simple adjustments generally necessary, knowledge of which may prevent any amount of trouble. I have frequently noticed queries in *The Motor Cycle* relating to the repair and adjustment of these gears, and so in the hope that they may be of use to other users I venture to offer a few hints which I have gleaned after over five years' use of the N.S.U. gear on a sidecar outfit.

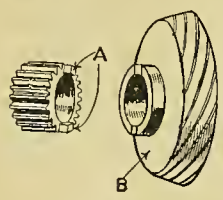


Fig. 1.
Central sun wheel and inner clutch cone.

Gear Slip.

Top gear slipping may be due to any of three causes, (*a*) clutch cone bottoming, (*b*) weak spring, or (*c*) operating bar tight. My experience as regards condition (*a*) is that the cone wears to an absolutely inappreciable extent, owing to the excellent design, and the main part certainly never bottoms. It is quite possible, however, for it to come up against the sun pinion, though this is very easily cured. The pinion in question is shown in fig. 1, together with the cone. The bottoming occurs at AA, the ends of the dogs on the pinion, and these may easily be ground down. I find that a clearance of 0.04in. is satisfactory. If there is real bottoming of the main part of the cone B, it will be shown by bright rings where the ends of the planet wheel spindles, which are not quite flush with the surface of the back of the female cone, have rubbed. Under these circumstances a new cone is, of course, necessary. The face B and ends of spindles referred to are untouched in my gear after five years' hard sidecar work. The coned rim will not bottom, since the inner cone is arranged, as shown in fig. 2, with plenty of clearance at C.

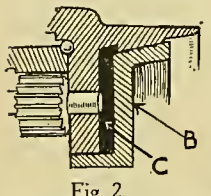

Fig. 2.
Clearance should be left at C to prevent the cone B rubbing on the planet wheel spindle.

With regard to slipping due to weak springs, I have never renewed the spring in my gear yet, and it appears to be quite strong enough.

I have had the usual trouble caused by a tight operating bar, and have had to grind down the inclined surfaces on the fork. After a time this can no longer be done, and a new fork or new top gear cone clutch is necessary. It is almost impossible to produce the same effect by reducing the diameter of the operating bar, as there is practically no lateral clearance and jamming results. The dismantling or assembling of the N.S.U. gear is always regarded as a tricky operation, principally on account of the spring. With the aid of a lathe it is very simple. The most important parts to be dealt with in assembling or dismantling are as follow, and are clearly shown in fig. 3 :

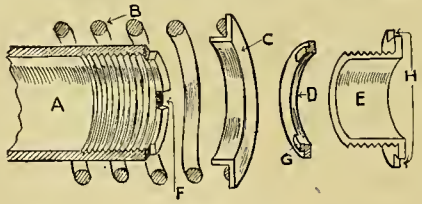

Fig. 3.
Section of the main shell on engine-shaft, showing spring, spring washer, and slide.

A Main shell fixed on engine-shaft by nut working inside part A.

B Spring.

C Spring washer, slides on outside of part A.

D Locking washer. Dogs G (two) fit inside C, being of same (outside and inside) diameter as tube A, and engage in two of the four slots F. Note outside diameter of D is about $\frac{3}{16}$in. less than that of C.

E Main locking nut screws in A, and is turned by tool engaging in slots H. Note outside diameter of E is same as that of D. Note also that E is of such a length that the gear can be withdrawn from crankshaft by unscrewing central nut, a shoulder on which engages against the inside edge of part E.

Assembling the Clutches.

The great difficulties are :

(1.) To compress the spring and engage the threads of E and A. Note that the slots F make it very easy to cross the threads.

(2.) To get dogs G in slots F. The latter are hidden by C when the spring is compressed.

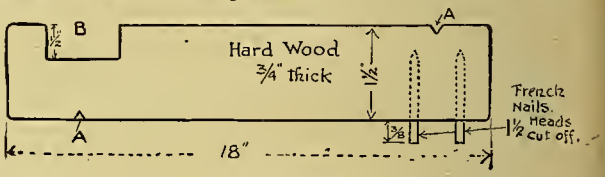

Fig. 4.
A useful tool which enables the gear to be dismantled with a minimum of trouble.

A Useful Tool.

A useful tool, which can be made in ten minutes and used in conjunction with a lathe, enabling the gear to be dismantled, cleaned, oiled, and reassembled in half an hour, consists of a piece of hard wood, its construction being clearly seen in fig. 4.

The french nails are at a correct distance apart, and fit in slots H (fig. 3) of nut E. The jaw B is of such a width that it will pass over the outside of D and E, but not over C. AA in the wood are centre punch holes for the tail-stock centre of the lathe.

Knock off the ring from the gear which keeps the outside stationary ring in place and remove the latter. Mount the gear in the lathe as shown in fig. 5.

It will be found that the first step of the drill jaws of a 3in. Cushman chuck will grip the inside of the pulley well enough, but pressure must be kept on the right-hand end of the gear by the tail-stock *via* the tool just described, the nails C of which are engaged in the slots of the nut E (fig. 3). Reverse the lathe by pushing the top of the pulley of the

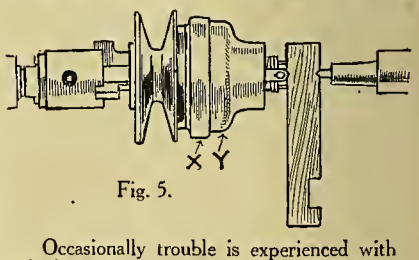

Fig. 5.
Occasionally trouble is experienced with the locking ring slipping. A remedy is to fit a screw through the main case and the ring.

Overhauling an Engine-shaft Gear.—

gear with the left hand, and decrease the pressure of the tail-stock gradually, keeping the nut stationary by means of the tool. The gear may then easily be dismantled.

To reassemble, remember first of all to put the nut holding the gear on the crankshaft inside A (fig. 1). Assemble the parts in the order shown (B, C, D, E), compress the spring by means of tail-stock *viâ* tool, as shown in fig. 5, and very carefully engage E and A (fig. 3). There need be no pressure on E if the nails C in the tool are long enough to go through the slots H and press on the face of D. Beware of crossing the threads. Screw up till tight, and then back half a turn. Reverse the tool so that the jaw B in the tool compresses the spring *via* the washer C, leaving D and E free. Compress the spring until slots F in A appear. Engage dogs G in D with slots F by pushing D round with a piece of wire, and screw E up (using same wire and slots H) sufficiently to prevent G and F becoming disengaged. Reverse the tool and screw E up tightly. E must be screwed right home, otherwise it may foul the operating bar and cause clutch slip.

Lubrication.

If a lathe is not available, a vertical drilling machine could be used with a slightly different tool.

For lubrication use ordinary engine oil. On an N.S.U. machine the gear gets some oil from the crank case release in the centre of the shaft, and one thorough clean up and oiling will last months.

I have had trouble with the locking ring which locks the main ball bearing adjustment (marked X, fig. 5). This refused to keep tight. I cured it by drilling and tapping a hole right through it and the main case of the gear (marked Y). A screw through the two (a tight fit) cured this fault permanently.

My experience of the gear on all other points is that it is absolutely satisfactory, and it is a pity some British manufacturer does not make an English version of it. ALPHA.

Steel Cylinders of German Aero Engines.

SUPERIOR EFFICIENCY DEMONSTRATED.

THE desirability or otherwise of fitting steel cylinders to motor cycle engines is a subject which has of late led to some controversy in our correspondence columns, and there appears to be a diversity of opinion as to whether the designer of one highly efficient motor cycle engine, notably the A.B.C., is following justifiable lines in the face of modern research by adopting steel cylinders. *Apropos* this controversy, an article appearing in the current issue of our contemporary *The Automobile Engineer* should be of especial interest to motor cycle designers. This article is the fourth instalment of what is undoubtedly the fullest technical description to be published in this country of the German Aeroplane Engine Trials, which took place just prior to the war, and whilst setting forth many points of deepest interest as regards lubrication, carburation, cooling, etc., of high efficiency air-cooled engines, it indicates forcibly the possible merits of the steel cylinder. In the following paragraph we propose briefly to review those portions of the article which bear upon this important point.

High h.p. per Unit of Capacity.

Passing on from the subject of dissipating heat from the piston—on which score it is pointed out that if insufficiently cooled the crown of the piston becomes red hot, with the result that serious lubricating troubles arise—the writer continues: "From this it follows that the cooling of the cylinders is most important, and one of the most interesting lessons learned from the trials was the value of the steel cylinders which were used in one engine, whereby the thickness of the wall could be reduced and better cooling obtained. The engine which was fitted with steel cylinders actually showed the highest horse-power per unit of capacity, which bears out these conclusions."

In this competition a four-cylinder engine won the first prize, and owing to the fact of low weight per horse-power (which involves fuel consumption, and necessitates compactness of the power unit), most of the entries were four-cylinder engines. The six-cylinder engine was at a disadvantage owing to its increased length of piping, greater overall length, its larger number of bearings and detail parts, and, adds the writer, "It was only on account of the better cylinder cooling, due to the employment of steel cylinders, that the six-cylinder engine was able to take second place."

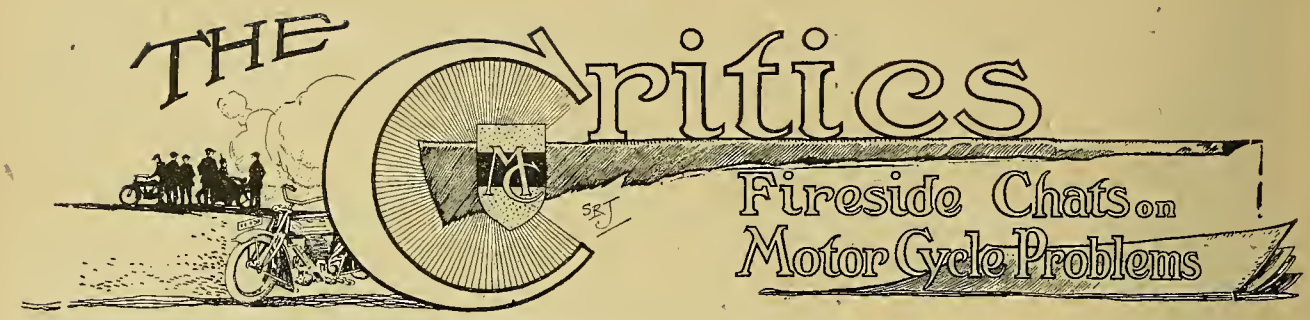
A Striking Testimony.

Summing up the results of the trial, the writer in our contemporary says: "One of the most striking lessons obtained from these trials was the advantage gained by using steel cylinders. In consequence of the thinner cylinder walls available the compression could be raised without affecting the pre-ignition point, and therefore the mean effective pressure was higher."

The Germans have no doubt exhibited an exceptional capacity for investigating technical matters, especially those which may have a possible bearing on the subject of military efficiency; that they have spared neither trouble nor expense would seem to warrant that, whatever decisions these trials may have brought about, such decisions were not hastily arrived at, but were the result of long research and practical experience. Motor cycle designers have already learned much by following the development of the aero engine, but we have still much to learn, and now, while neither money nor labour is being spared in the gigantic struggle for supremacy, is the time when the British manufacturer should sit up and take notice. The cost of production is, of course, a vitally important point, and it yet remains an open question whether or not the advantages of the steel cylinder are sufficient to outweigh its high cost of manufacture.

BOVINE CURIOSITY.

The Indian sidecar belongs to Marcel Krieger, of Geneva, who is, we understand, attached to the British Ministry of Munitions. He snapped the cattle, who appear so keenly interested in the combination, whilst on an excursion in the Swiss mountains. Observe the surface of the road; it proves a motor cycle's capacity for negotiating even wild mountain tracks. The picture was taken at an altitude of 5,400 feet above sea level. No wonder the cattle were surprised!



IT was the Novice who kicked off with the pertinent enquiry, "Why do manufacturers produce sidecar outfits costing, say, £115, when one can get a full-blown four-wheeler car at that price?"

The question was evidently shot at the Manufacturer. "It is not that they aim at a sidecar outfit costing £115," answered the latter, "but that they aim at producing a tip-top vehicle complete in every detail, which cannot be made at less."

"Good!" agreed the Novice. "But do you imagine that sidecars of this kind will hold their own against the low-priced light car manufactured on the quantity basis?"

Looks versus Upkeep.

"Unquestionably they will," replied the man of practice. "You people who talk about the cheap quantity produced car must not imagine that the motor cycle manufacturer is asleep. He also is going to produce in quantities, and, given the same systems of manufacture for both, the motor cycle outfit will always remain considerably cheaper than a car of the same quality. Then, again, you want to remember that purchasing cost is by no means everything. The sidecar outfit costs infinitely less in oil, petrol, tyres, storage, and taxes than any car. Ever since its appearance people have predicted its failure, yet practice has proved it to be a highly desirable type of machine. Where one man can afford £1 a week running expenses, fifty can spare 10s. for their motoring pleasures."

"Take the case of the beginner," the Novice argued, "the man in the street. He sees two vehicles at approximately the same price. One offers him a cushioned seat, security from the weather, the comfort of a windscreen; while with the other he knows that he will have to don overalls, and that even then he will be exposed. Which is he going to buy? I say he will plump for the four-wheeler every time!"

Quantity or Quality?

"Not *every* time," interposed the Manufacturer mildly. "Only the first time. You see it is all a question of quality. The beginner has no taste, but, as a rule, he acquires it. Thousands never acquire it, but the majority do. And next time they ask themselves, 'Which am I going to have, the best of one type or the cheapest of the other?' That's what it amounts to. One is the cheapest of its class, the other the best and the most costly. Which is the man with a year's experience of machinery going to choose? Besides, some will burn their fingers over the running cost question."

The Novice looked appealingly at the Journalist, whose summaries were usually fairly judicial.

"I must say I agree with everything so far," said the somewhat sleepy man of letters in response to the unvoiced enquiry. "It's a question of best or cheapest. It is physically impossible to produce a first-class four-wheeler, however light, at the same price as you can produce a first-class sidecar outfit. The car which is to compete with the sidecar outfit in price can only do so at the cost of quality. The power unit and the transmission may be sound, but pennies and sixpences are pinched at every nook and corner. The consequence is that when you try the two compared vehicles on the road there is—well, you cannot compare them! In the case of the car you are surrounded by an atmosphere of cheapness which hits you where you live every time you take the wheel. Probably you have some little pride as a motorist, and, to put it plainly, you are a little ashamed of the vehicle. On the luxurious sidecar outfit, on the other hand, you have the secure feeling that the machinery under you is of the best, while the running of the outfit is infinitely preferable."

The Weight Question.

The Novice sucked hard at his pipe. The Manufacturer rejoiced in the sensation that for once popular feeling was with him. But the D.R., hitherto silent, felt it was about time he contradicted someone.

"I do not agree," said the D.R., "that one is necessarily ashamed of one's cheap car. The Journalist is evidently thinking of alien products he has been called upon to test in his dark hours. My Humberette and my Jowett were machines I was always proud of. They cost, so far as casual judgment went, no more to run than the heavy sidecar outfit at £115. Good though it may be, I must say that the present day sidecar *de luxe* is unnecessarily heavy and massive. Why do manufacturers make it so weighty?"

"I will tell you," volunteered the Manufacturer. "In the first place, you demand electric lighting, which in itself is a weighty proposition. You demand everything of the best—a roomy sidecar, windscreen, body box, luggage grid. You want a spare wheel, chain drive, and at least three speeds. Finally, you want enough power to enable you to leave the cheap cars behind, while the sidecar attachments must be sufficiently strong for all conditions—Colonial, mountaineering, and Six Days trials. If you can tell me how you can appreciably lighten present day design, yet retain all this, you will be doing a service to mankind."

The Light Sidecar Outfit in Favour.

"I wouldn't try," responded the D.R. blithely, flinging a match into the fire. "I should realise that I was up against a knotty proposition, and I should try to evolve something different. If I had to choose, I should pick the light car on the lines of the Humberette in preference to the complete sidecar outfit every time. I do not want a Rolls-Royce on three wheels because it is neither a real luxury nor a real economy vehicle. In other words, your heavy sidecar outfit falls between two ideals"—at last the D.R. was in his element—"It falls short of one without attaining the other. It is too good for rough utility, yet no one can call the wearing of overalls a luxury."

"In my opinion," put in the Journalist, "it is not the quantity produced four-wheeler, but machines on the lines of the new Scott Sociable and the Morgan that manufacturers of luxurious sidecar outfits will have to fear. The heavy sidecar outfit consists of two units built up as an inseparable whole. The motor cycle is not practical as a solo mount, and the sidecar, ordinarily speaking, is a permanent fixture. If, then, the sidecar is a permanent fixture, why not build it as such, and give the driver the same comfort and shelter as his passenger enjoys? Why not make a three-wheeled engineering job of it?"

"That, exactly, opens up my point," added the D.R. "The sidecar outfit is essentially a *combination*. Then let it possess the advantages of a combination. What are its recommending features? Lightness, detachability, convenience, and economy. Suppose, now, we divide the purchasing public into three classes—." He paused, that his words might gain their full significance.

"Strong, mild, and medium?" quietly suggested the Novice.

"No!" stated the D.R.

"Mild, bitter, and Scotch?" proposed the Journalist.

Which Demand Predominates?

"No," repeated the ex-soldier, resenting the fact that, in his most serious moods, other people always seemed the opposite side out—"Poor, medium, and rich. The poor man rides a lightweight to and from business. The medium man is the multitude. He is the man who chiefly concerns us. He wants a machine suitable for business or pleasure—something he can ride himself at rock bottom cost, yet on which he can take his wife out during

The Critics. –

week-ends and holidays. *He* is the sidecar man, and let us consider what he wants—not necessarily what he is induced to buy.

"If he is going in for a sidecar outfit," the D.R. went on, "it must be a double-purpose affair if he is to get maximum results from it. Whether it is 3½ h.p., 4 h.p., or 6 h.p. matters little. He wants a machine he can ride solo when necessary, not only because it is cheaper to ride solo than with a sidecar, but because he may have to leave the machine in any passage-way or even in the cycle shed at the office. Then when Saturday comes he wants to be able to attach his sidecar in five minutes and take his wife or his best girl out for a spin."

"I quite agree," the Journalist backed him up. "I think the greatest demand is for the light sidecar attachment. That is the *true* sidecar outfit, and what we want is perfection in quick detachable couplings, instead of which they appear to become more and more complicated."

"Lastly, we come to the comparatively wealthy purchaser," the D.R. pursued. "He goes in for two machines, one a general runabout and business hack, the other for comfortable touring. The heavy sidecar outfit falls short of one without attaining the other, and so he buys the two extremes—the lightweight and the light car."

Both Types Popular.

The Manufacturer had pondered all this in silence, but now he spoke. "All of which is true so far as it goes," he said, "but you have not stuck to the point. You have merely pointed out the possible usefulness of the light, quick detachable outfit. All agree that it is an extremely useful type. There are thousands on the road to-day which cost £60 to £70 complete, but my answer to your argument is that there are also thousands of the heavy *de luxe* patterns. Surely the test of the pudding——? You yourselves know numbers of riders who start off with the comparatively light outfit, but next year or the year after they buy the heavy outfit *de luxe*. This, indeed, is the common order of things, and, while amateurs and journalists can dwell upon their ideals, manufacturers have to stick to the facts of common demand and practice. The sidecar *de luxe* is tried and tested. It has made good. Ye gods! do you imagine manufacturers are asleep over the problems on which their living depends?"

A Stony Path.

The Novice had evidently something to say, for he had been fidgeting and brushing his waistcoat for the last few minutes. "You are all a bit biased in your views," he now announced. "You are purely motor cyclists, whereas I have a light car in addition, so would like to air my views from the point of the light car man in the street. I think that the cheap light car, which may hit the sidecar outfit, has an exceedingly stony path to tread. Firstly it has to overcome the prejudices of men like yourselves—motor cyclists, and—should we say?—sportsmen. It cannot be of the same high workmanship at the price as the sidecar outfit, and therefore you turn your backs to it. Then again, it is not so fast, and so on. You all think the same way; and so, in the past, the cheap four-wheeler has missed your class—the *mechanical* class, and has fallen into the hands of the *unmechanical*, like myself: men who buy from the bill boards, and who would jigger up your luxurious sidecar outfit. Thus the cheap car has got its bad name—not because it is an imperfect proposition, but because it is the one proposition that appeals to the imperfect driver."

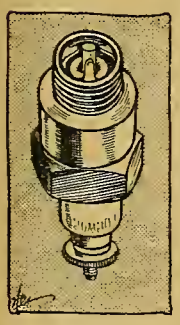
The D.R. congratulated the Novice on having "come out quite sensible."

"But," added the Manufacturer, "we do not get away from the problem of quantity or quality for money. No one doubts that the few cheap light cars we have are excellent value, but the material fact remains—that *it is humanly impossible* to produce a four-wheeler at the same price as one can produce a sidecar outfit. The only four-wheeled specialised product we have does not fill the bill from the point of view of the British manufacturer. From his standpoint it has drawbacks, though it is undoubtedly a marvellous production. It has a two-speed gear—a proposition our buying public would not look at. Its ponderous flabby engine—which renders this gear possible—is heavy on oil and petrol. If this machine had been compelled to attain its first market in England it would never have combated British prejudice. Indeed, we have produced better propositions in England, which have failed, simply through British lack of appreciation for the rough and serviceable."

The Journalist finally summed up the situation by saying that he did not think there was any question of supersedure about it. The light sidecar outfit, the outfit *de luxe*, and the cheap light car would each continue to find its appreciative markets. Each had its place, and so the controversy left him and his companions at the exact spot from which they had started. And there, with apologies, we fear we must leave the reader.

THE LATEST FORWARD PLUG.

WE have received a sample of the latest pattern Forward plug, made by the Forward Motor Co., Summer Row, Birmingham, known as the Type A, which is fitted with the company's patent enamel joint, which has been exclusively used in the Type C plug for some time. This joint is absolutely and permanently gastight, and will not leak under any circumstances. There is no gland nut to work loose, and no asbestos in the construction of the plug to shrink. The plug is of the three-point variety, has substantial electrodes, and should be entirely satisfactory in a motor cycle engine. The central electrode has the threads taken off the upper end so that the terminal screw can be quickly slipped in position or rapidly unscrewed without the danger of dropping off at the end of the thread—a good point.



A new Forward plug fitted with the company's patent enamel joint.

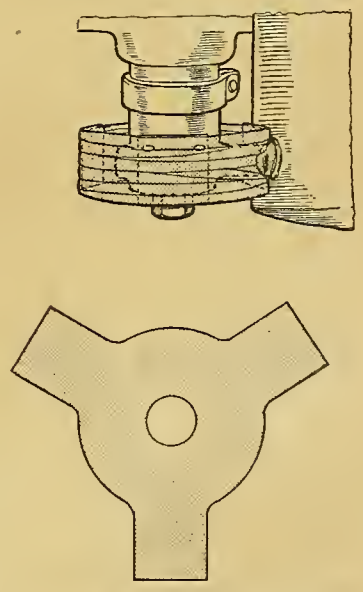
CARBURETTER DRIP CUP.

IN cold weather it is generally necessary to flood the carburetter freely—especially in the case of a two-stroke—ere a start can be made. This generally means that a good deal of fuel drips from the jet air holes, and of course runs to waste, without in any way assisting in the operation of starting up. By means of a very simple fitment, which anyone can make in five minutes, this overflow of fuel can be utilised to assist very materially in starting the engine.

The device, as the writer has fitted it to his own small two-stroke, is made as follows: Obtain a piece of thin flat tin of the requisite size, and cut it into the shape shown in the sketch, so that it represents a three-spoke rimless wheel. Make a hole in the centre of the hub portion just large enough to take the jet screw; then, having fixed the device to the carburetter by means of this screw, bend up the three arms so that they overlap the air holes. Now wrap a few inches of black linen tape round the outside of the three arms, so as to form a cup round and under the air holes.

On flooding the carburetter the overflow is now caught by the cup and totally absorbed by the linen tape, forming, as it were, a pocket of very rich gas as long as evaporation continues. The writer has found that this little fitment, applied to a small two-stroke, in addition to saving petrol, entirely eliminated all starting difficulties in cold weather, and when warm weather comes the tape can simply be cut away.

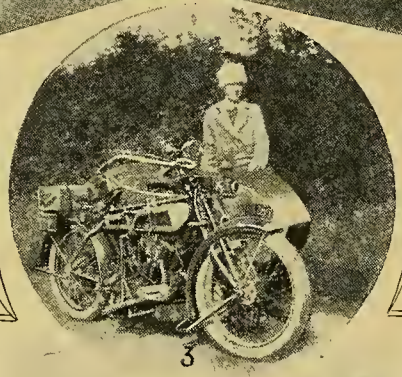
CHINOOK.



A carburetter drip cup, a simple contrivance to effect economy.

A JAUNT TO THE WELSH MOUNTAINS.

Memories of a Ten Days' Tour for £10 'midst the Finest Scenery.



(1) A typical Welsh mountain road—the picture well conveys the desolation and loneliness of these highland districts. (2) Remains of the old Roman wall at Uriconium, near Shrewsbury. (3) The writer and the A.J.S. combination on which the tour was accomplished. (4) One of the most characteristic of the beautiful old half-timbered houses—the Feathers Hotel, Ludlow.

WHEN we decided to take a tour of this much-discussed holiday ground, we thought it wiser to obtain a definite route for reference, and not depend solely on signposts and maps.

We therefore availed ourselves of the services of the A.A. and M.U., who not only supplied us with a route, but also helped us to avoid bad roads and itemised various points of interest.

A certain sunny morning found us dodging the bad traffic and roads out of London. Our route lay through Tring, Aylesbury, Bicester, Middleton Stoney, Bourton-on-the-Hill, down Fish Hill into Broadway. The two last-named villages are exceptionally quaint, and we were tempted to linger and explore, but time did not permit, so we followed the fascinating Vale of Evesham into Pershore.

Minor Troubles.

It was between here and Worcester that we got our first little whisper of trouble. The sidecar inner tube slit, and before we stopped the valve had broken away, so that we were able to appreciate the advantages of a detachable wheel. A picnic tea followed, and a sprint into Worcester gave us time to ramble around the town. Queen Elizabeth's House, Edgar's Tower, and the Cathedral were in turn appreciated.

Next morning we wended our way to Great Witley, Tenbury, and mediæval Ludlow, where we stayed to admire the beautifully wooded and carved front of the Feathers Hotel. We followed the Shrewsbury Road until we reached Brompton, turning left at the "Bluebell Inn" for Sarn Kerry and Newtown. We were always uncertain when we actually entered Wales, but the scenery throughout was ever-enticing, the high misty hills drawing nearer and nearer.

The afternoon seemed to be fated to be one of trouble—of a minor order. We had rain galore, a choked oil pump, followed by the plugs oiling up, the results of efforts to avoid the worse evil of seizure. Then a high-tension wire fouled the exhaust pipe, causing a short circuit, and, to crown all, one cylinder cut out, and the dusk found us in a very dreary little village. Water seemed to be everywhere, and its presence in both the magneto and the carburetter had put us out of action. However, persistence on the part of the driver eventually settled the trouble, and we continued through the semi-darkness and pouring rain to Cemmaes Road, where we found accommodation.

It rained all night, but morning sunshine welcomed us to the road once more.

A Welsh Market Day.

Leaving Cemmaes Road, we ran amidst scenery more typically Welsh, and Machynlleth, the next town, we found particularly interesting, as it was market day. The streets were full of Welsh ponies, cattle, and sheep, which apparently roamed about the place at will.

A Jaunt to the Welsh Mountains.—

Aberdovey, Arthog, Dolgelly to Barmouth showed us more wild and beautiful scenery. Barmouth, the finish of the day's run, did not strike us very favourably. It was charmingly situated, but the town itself was too suggestive of trippers. The coast road from here to Harlech was certainly interesting, but the gradients and a forty-knot nor'-wester called for second gear most of the way. Amidst mediæval castle and rough stone houses, the presence of a modern motor cycle seemed to be an anachronism. After Harlech there seemed little of interest until we turned left at Maentwrog for Penrhyn and Tremadoc. Then the gorgeous Snowdon scenery unfolded itself gradually.

Lunch by the River.

Perhaps our jolliest lunch was on the banks of the River Glaslyn. It is almost impossible to describe adequately the magnificence of the scenery on the road to Beddgelert. The gem is undoubtedly Pont-Aberglaslyn. The quaint old bridge spanning the turbulent waters, the lovely wooded hills on either side, made a most impressive picture. Nestling in a valley, and surrounded by vast mountains, their bleakness softened by the afternoon light, came the village of Beddgelert. Here we made a pilgrimage to see Gelert's grave, but it was somewhat disappointing, as we expected to see something more than just a crude piece of stone.

Llanberis and Snowdon.

An easy run from the village, beside Lyn Dinas and Lyn Gwynant, led to the long pull up the Gwynant Pass to Pen-y-Gwryd, with the valley lying far below on the left and the Llwydd and Crib Coch shoulders of Snowdon beyond it, forming a glorious mountain panorama. We turned sharp to the left at the hotel, and, still climbing, soon reached the top of the Llanberis Pass. Here the rain made us appreciate the shelter given by a huge slab of rock which had slid from the mountain side, forming a natural cave. We arrived at Llanberis in time to see the falls before night. The next day was spent in climbing Snowdon, which, with its customary elusiveness, hid its head in the mist all the time we were on the top and until we were back below the snow line. Leaving Llanberis in the evening, we climbed back up the pass to Pen-y-Gwryd, and on through the straggling village of Capel Curig, beloved of artists, to Bettws-y-Coed before lighting up. This village is undoubtedly the Mecca of all tourists in Wales, and we spent an interesting day exploring. Swallow Falls, Miners' Bridge, and Pandy Mill were duly admired. After the bleakness of Snowdon the verdure of this beautiful village was restful and refreshing. The following day we ran out to Lake Ogwen to explore its surroundings, of which we had heard so much. We left the sidecar by the inn, and walked by a winding track across the bog, to see what is probably one of the most impressive sights in Wales—Llyn Idwal, surrounded by lofty mountains. From here we had a feverish scramble over rocks and stones right up to the gloomy yawning base of the cleft in the rocks known as Twll-du (the Devil's Kitchen). More than one fatal accident has overtaken the zealous climber who has tried to scale its slippery sides. That night found us peacefully reviewing Borrow's beloved Llangollen.

From 6 h.p. Sidecar to 1 h.p. Barge.

The next day we changed our normal mode of transport for a 1 h.p. barge, which takes one out to Valle Crucis Abbey. This interesting ruin, dating from the eleventh century, contains a stone coffin of one of the Knight Templars. Another relic of special interest is an old well, into which you may throw your pennies and wish, on the principle of heads you win, tails you lose. We shrewdly suspect that the winner every time was the lawful denizen who periodically collects the pennies.

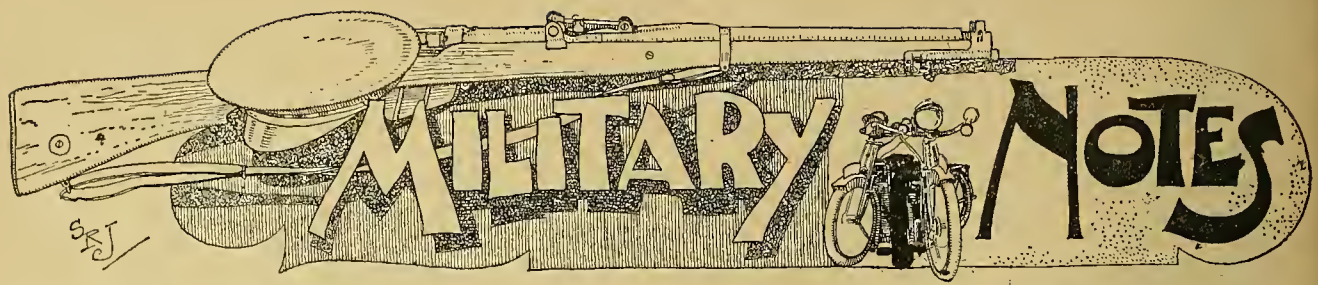
The old wooden trestle bridge across the Afon Glaslyn at Beddgelert. This district abounds with magnificent mountain scenery.

From Llangollen to Shrewsbury the scenery became more ordinary—in fact, the terrible condition of the roads was more enforced upon us than the surroundings. On Sunday morning we made for Uriconium. These little known remains of a Roman city held us entranced. The most interesting relics were the baths, and we lingered quite a time. After taking a photograph of the partly demolished wall, we made for home *via* Stratford-on-Avon.

Summary.

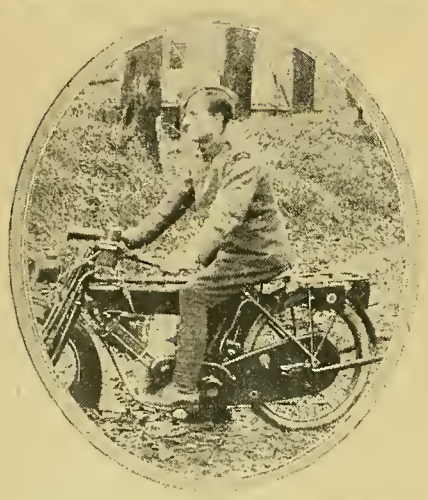
Time, ten days; total mileage, 550; consumption, 55 m.p.g., half petrol, half white spirit; machine, 6 h.p. A.J.S. Our total expenditure was under £10. Needless to say that picnicking enabled us to have a more dainty and varied *menu*, and at the same time represented a saving on hotel expenses.

"THE PASSENGER."



D.R. KILLED.

WE are advised by his relatives of the death of Sec.-A.M. L. L. Bailey, R.F.C., formerly of Widnes, who was accidentally killed whilst carrying despatches in France. Bailey joined



2nd-A.M. L. L. Bailey, R.F.C., accidentally killed whilst carrying despatches in France.

up in May, 1916, and has ridden a good deal in France. He was buried in Bailleul Cemetery.

MOTOR CYCLIST ATTACKS ZEPPELINS.

CAPT. J. W. WOODHOUSE, M.C., who, we mentioned, has recently had a bar added to the Military Cross, received this distinction "for conspicuous gallantry on three occasions in attacking Zeppelin airships over land and sea."

APPOINTED NAVAL CHAPLAIN.

THE Rev. P. W. Bischoff, formerly a member of the committee of the A.C.U., who interested himself very keenly in the use of motor cycles for military purposes long before the war broke out, and who competed in several Scottish motor cycle trials, has been appointed an acting chaplain for temporary service in the Royal Navy.

BELGIAN DECORATION FOR MOTOR CYCLIST.

WE are happy to be able to state that Temporary Lieutenant D. S. Baddeley, A.S.C., formerly one of the leading lights of the Motor Cycling Club, has been created by H.M. the King of the Belgians a Chevalier de l'Ordre de la Couronne.

A MEMBER OF THE BLACK CAT TANK.

WE regret to announce that a member of a famous "Tank" crew passed away during the performance of an operation. The man in question is Gnr. W. W. Atkins, who had been ailing with a cold for a few days previously, and had, in fact, only just rejoined after being discharged from hospital as the result of a wound he received whilst getting out of his "Tank" after a cruise in the German lines. Gnr. Atkins formed one of the crew of the first heavy armoured cars to cross the German lines, his commander being Lt. H. C. F. Drader, M.C., who adopted the famous black kitten—now practically cat size—as a mascot. Gnr. Atkins was formerly employed by Mr. W. Brandish, motor agent, Foleshill Road, Coventry, and was recruited through *The Motor Cycle* for the Motor Machine Gun Service, being subsequently transferred.

Gnr. W. W. Atkins and the crew of the now famous Black Cat Tank. This Tank is to be seen in the great Ancre film, the Black Cat figuring prominently in the picture.

A CHAT WITH AN AIRMAN MOTOR CYCLIST.

THE other day we had the pleasure of a chat with Capt. Vernon Busby, R.F.C., who was formerly a despatch rider with the Royal Engineers, subsequently receiving a commission in that

Capt. Vernon Busby, R.F.C.

section and then a transfer to the R.F.C. As may be imagined, Capt. Busby has had a very varied experience. During his sojourn in France as an airman he had opportunities of flying and testing nearly all the different makes of aeroplanes and engines used in the British Army. He remarked upon the strong attraction that the Flying Corps had proved to old motor cyclists, and mentioned a large number of men with whom he had come in contact. He was at the depot, and met personally four greatly respected motor cyclists who have lost their lives for their country whilst flying, notably Sec.-Lt. O. C. Godfrey, Sec.-Lt. John Gibson, Sec.-Lt. G. L. Columb, and Sec.-Lt. R. H. Edwards. For some weeks past Capt. Busby has been home on sick leave, having been troubled with sciatica, but hopes shortly to rejoin his squadron. He is full of enthusiasm for the possibilities of the motor cycle and light car trades in particular after the war.

A DISTINGUISHED OFFICER.

COL. E. D. SWINTON, D.S.O., has been created a C.B. He was one of the men responsible for the development of the "Tanks." Col. Swinton is a well-known author, who wrote under the name of "Old Luk Oie," and was also the original "Eye Witness" to the British troops in France. It is not generally known that he acted as observer on a German car in the Prince Henry Tour.

Ariel

When you see a motor cycle branded with this trade mark, it's the Ariel—by achievements the machine of supreme and unchallenged reliability.

32-Page Art List post free.

ARIEL WORKS LTD.,

3, BOURNBROOK, BIRMINGHAM.

They are British-made

IT is against the National interest to purchase imported Tyres in War time. All the money is needed in the Country.

Wood-Milne Tyres are not to be beaten for Price or Quality. The Winter is coming on, and you want a really reliable Non-skid. We have it.

Wood-Milnes give better service, and cost less per mile, and are made in sizes suitable for every type of machine.

Let us send you our illustrated Booklet. It tells you all about them.

TRADE MARK WOOD-MILNE

THE ARBUTHNOT TROPHY.

THE statuette of the late Rear-Admiral Sir Robert Keith Arbuthnot, Bt., K.C.B., M.V.O., was the outcome of a suggestion of a member of the staff of this journal that the memory of this gallant motor cyclist should be perpetuated by means of a trophy to be competed for annually by officers of His Majesty's Navy.

Many subscriptions were received for the fund, which was instituted to purchase the trophy and bear the expenses of a competition of this kind, and motor cyclists from all parts of the globe, and in all stations of life, sent in their contributions.

The work of executing the statuette was entrusted to that well-known sculptor, Lady Scott, who was a pupil of the eminent French sculptor M. Rodin, and widow of the late Captain Robert Falkland Scott. Though Lady Scott had never met Sir Robert Arbuthnot she was able to get a very fair likeness of his features, and altogether has accomplished her task most successfully.

The Arbuthnot Trophy.

It will be noticed that the late Admiral is garbed in his motor cycling attire, and is wearing the poncho which was such a familiar object in the principal competitions in which he competed.

IN MEMORY OF A GALLANT SAILOR AND GREAT MOTOR CYCLIST.

AN A.C.U. RESOLUTION.

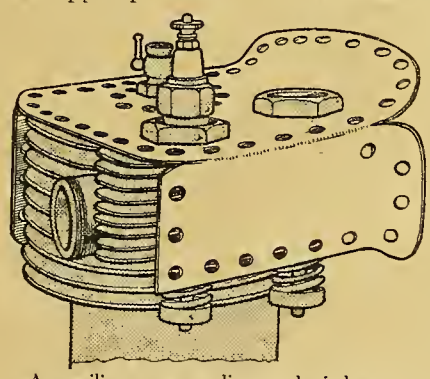
AT a meeting of the A.C.U held on the 15th inst. the following resolution of the Competitions Committee was adopted: "That in all open competitions promoted by the Union other than those of an international character no motor cycle having any part of German, Austrian, Bulgarian, or Turkish origin or manufacture, and no entrant of such nationality shall be eligible to compete. This shall not apply to a motor cycle manufactured before August, 1914." New members were elected, and the Kirkee M.C., India, was affiliated to the Union.

AN AUXILIARY COPPER RADIATOR.

How a Rider can keep his Engine Cool.

FROM time to time *The Motor Cycle* has given descriptions of various auxiliary radiators evolved by practical riders—the Harcourt people being, I suppose, the pioneers in this line of invention. Later Capt. Lindsay described a copper plate fitment he had attached to his Norton, and it was this idea that led the writer to experiment with similar fitments.

Copper radiators are by no means so ugly as those of aluminium—indeed, when decently burnished, they rather add to the good appearance of the power unit Artistic perforations, though theoretically wrong, add the finishing touch as regards appearances, while if desired the surface of the copper can be kept clean and bright. But what is more to the point, better running can be obtained and oil saved by the judicious use of these fitments, while on some machines they may add months to the life of the sparking plug.



An auxiliary copper radiator and wind scoop with ample and effective cooling surface.

The accompanying illustration explains a type of auxiliary radiator the writer has recently carried into practice. Its primary object is to intercept and dissipate the heat passing from the cylinder to those massive and heat-retaining chunks of metal, the valve caps, sparking plug, and compression tap, while its secondary purpose is to act as an air scoop, catching the current of air and concentrating it upon the cylinder head.

A sheet of copper of the required measurements is cut into the shape shown in the sketch, and cut to take the valve caps and the compression tap. The exact position of the holes can be ascertained by careful measurement, but a safer plan is to cut out the hole for the compression tap in the centre of the plate, and, having temporarily attached the sheet to the cylinder, mark out the respective positions of the two valve cap holes by tapping lightly with a hammer (having, of course, first removed the caps). The radiator can then be drilled, if desired, the ring of holes round the top being the only ones that answer any purpose beyond ornamentation, and finally the sheet is bent into the desired curves as indicated by the accompanying drawing. The copper and asbestos joint rings lie between the cylinder and the radiator, and it will be noticed that all the edges of the fitment that meet the rush of air are curved to concentrate the cooling draught on the cylinder.

This radiator dissipates a considerable amount of heat and also acts as an air scoop. With the machine stationary and the engine running, it would perhaps tend to imprison a certain amount of hot air round the cylinder, but this point can, I think, be neglected, as the ring of air holes permits the hot air to escape from the top of the radiator.

CHASING THE SENUSSI.

ANOTHER MOTOR-ASSISTED BICYCLE.

"THE CRITICS" ON SIDECARS VERSUS LIGHT CARS.

Club President Honoured.

Mr. George A. Touche, M.P., who received a knighthood in the last honours list, is president of the Finsbury Park Cycling and Motor Cycling Club.

Explosion Victim's Progress.

T. J. Ross, captain of the Woolwich Club and Triumph agent, who received injury through the East End explosion, is making good progress. A member of the Woolwich Club whose home was wrecked by the explosion is now installed in new quarters—in another district.

Clynos after the War.

From a paragraph in the last issue, several readers have been led to think that Mr. Hugh Gibson, the erstwhile competition rider, has severed his connection with the Clyno Co. This is not so; and the gifted rider is very much employed by the above-named company in keeping pace with ever-increasing Government orders for sidecars. Mr. Gibson is looking forward to visiting Clyno agents with the post-war Clyno sidecar model when present pressure relaxes.

A Brave Motor Cyclist.

It may be remembered that, on the occasion of the last Zeppelin raid over London, the fact of one of the two Zeppelins having come down in Essex afterwards was announced by a young Essex farmer, Mr. Albert Wright, who set off on his motor bicycle to inform the military authorities. While on the way he collided with a car, was severely injured, and eventually lost his life. It was announced last Wednesday that Mr. John Wright, the father of Mr. Albert Wright, the brave motor cyclist referred to, has received a grant of £150 from the War Office.

A Wintry Ride and Economy.

Two hundred miles to the West of England and back during the past week-end served to give us a further example of the economy of motor cycling. The journey was from Coventry, *viâ* Birmingham, Evesham, Cheltenham, and Gloucester, to Bristol, the return being over the same route to Evesham, thence through Bidford, Stratford, Warwick, and Kenilworth to Coventry. The conditions were not ideal, frozen roads being general, with hard snow around and south of Cheltenham. The down journey was pleasant, by reason of continuous sunshine, but the return was a cold, very cold, affair. The 3 h.p. Enfield gave no trouble, and simply romped along, the first stop after Birmingham on the forward journey being at Berkeley Road, seventy-five miles. An excellent average speed was maintained throughout. Road surfaces were hard to judge, but the last fifteen miles to Bristol are shockingly mutilated by motor 'bus traffic. The Warwick, Kenilworth, to Coventry section was also very bad.

The striking point of the trip lies on the score of expense. The Enfield is running at 100 m.p.g., and used almost exactly two gallons. At 3s. 4d. per gallon, this amounts to, say, 7s., plus 6d. for lubricating oil. Total running cost, 7s. 6d. The return rail fare is 27s. 6d. under present conditions. A clear saving of £1 is indeed a consideration in these days. Moreover, the time occupied was very little more than the quickest railway connection, with the advantages of fresh air and freedom thrown in.

War Time Developments.

As we have intimated from time to time, engineers have learnt more by the results of the war than would have been brought about by ten years of ordinary development. Things will move quickly when peace conditions return, and we can look forward to some big changes, especially in the air-cooled engine. The almost inconceivably rapid progress of the aero engine has opened up new fields as regards cylinder castings, etc., and one is tempted to think that overheating, at any rate, will be a thing of the past. Valves, too, have been improved, and the highly perfected valve of to-morrow, working in its cool running cylinder, will probably last indefinitely without attention.

Will Silence Follow?

But the aeroplane is teaching us nothing as regards silencing—a point on which there is ample room for improvement. Silencing the exhaust is a simple matter, but valve clatter presents a more knotty problem, and, unfortunately, the modern air-cooled cylinder, with its fine, deep, radiating fins, tends very much to enhance the ring of the valves.

British Magnetos in the Air.

It is officially announced that our airmen who have destroyed Zeppelins all used British magnetos designed in Britain and made by British labour in all-British factories.

Speeding Up.

Sidney George writes from France: "There is a little matter you might put right for me. In *The Motor Cycle* of February 8th you have me down as holding a high-speed record at nearly 93 m.p.h. Now this stands at 93.48 m.p.h."

Are Imports Prohibited?—No!

In March last imports of foreign-made motor cars and motor cycles were prohibited by the British Government, but during January (*i.e.*, ten months after the Order) no fewer than 201 motor cycles, valued with parts at £16,218, were allowed into this country. Why?

"The Critics."

Our new series of articles entitled "The Critics" will, we think, be keenly followed by many of our readers, as the object of these articles is to present all sides of the various and much discussed problems that at times perplex not only the novice but also the practical rider. The interest of the articles is added to by the fact that each is the result of an actual discussion, and the characters are real, living beings.

The Cheery Side.

We have received many bitter comments from readers on the stopping of petrol supplies for private motorists, but, disappointing though it may be, we must endeavour to look on the just and cheery side. If the war is to be prosecuted more vigorously and the danger of shortage in the Army avoided by these precautionary measures, we must accept the inevitable with a spirit of patriotism.

An Expensive Form of Economy.

A Portsea vicar was fined £2 on Thursday last for driving a motor cycle at 31¼ m.p.h. He wrote to the Bench explaining that he had to go to London on business for his brother in Mesopotamia, and he was economising by travelling by road instead of by rail. The journey of fifty miles took him five hours, and it was his first offence in fourteen years.

The National War Funds.

At the week-end the principal war funds stood as follow :

The Prince of Wales's Fund (distributed £3,539,719)	£6,032,027	0	0
British Red Cross Fund	6,190,753	0	0
Tobacco Fund	125,596	0	0

Marriage of Lt. H. C. Mills, R.N.V.R.

On the occasion of a smoking concert organised in the honour of Lt. H. C. Mills, R.N V.R., a presentation was made to his *fiancée*, Miss Dorothy Wilding, by Flight-Commander Owen, R.N. The marriage took place on the 10th inst.

Somewhat Vague.

A correspondent asks, without giving the original price of his machine, power, mileage, etc., what he ought to allow for depreciation with petrol at 3s. 6d. per gallon! We should say about 4d. or 9d. In other words, the answer is eleven.

The Year of Origin.

It has been brought to our notice on several occasions of late that advertisers of second-hand machines have wrongly stated the year of origin. In more than one instance a buyer has complained to us that he has purchased a machine purported to be a certain year's production, but which, on enquiry, proved to have been of a pattern in vogue the year previously. Motor cyclists would do well to be on their guard. *The Motor Cycle* Deposit System, whereby machines may be obtained on approval, was instituted to safeguard advertisers from all pitfalls of this nature.

The Motor Transport Volunteers.

A meeting, at which the Lord Mayor of London, Sir William Dunn, presided, was held at the Mansion House early last week in support of the Motor Transport Volunteers. The principal speakers were Gen. Sir Horace Smith-Dorrien, K.C.B., D.S.O., Lt.-Gen. Sir Francis Lloyd, K.C.B., C.V.O., D.S.O. (General Officer Commanding the London district), and Sir John Lister-Kaye (president of the corps).

The Motor Transport Volunteers, which are allied to the National Motor Volunteers, perform their duties between the hours of midnight and 7 a.m., their work consisting of meeting troop trains and conveying soldiers arriving by them to their destinations in London or from one terminus to another.

The speakers referred at great length to the extraordinarily valuable work carried out by this corps, which has greatly assisted troops in keeping fit, and has also helped to shield them from the many dangers which beset them on their arrival in London.

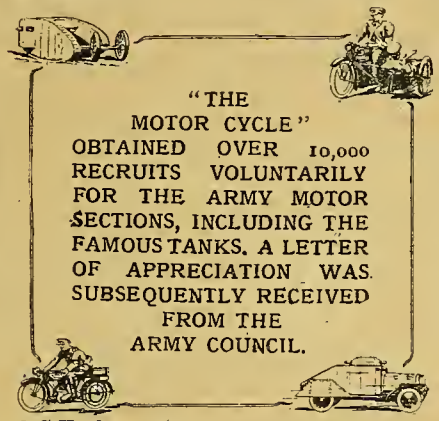
The corps is in need of men, money, and motor cars (heavy and light), and it would be extremely glad to receive the assistance of motor cyclists driving side-car combinations who could help in the work of transporting the troops, especially in cases where only one man requires to go to one particular place, and also acting as despatch riders between the various railway stations. If sufficient men are obtained, it is hoped that members of the corps would be required to undertake duty only one night in six, while petrol is supplied free for this service. Applications should be made to the Hon. Sec., Motor Transport Volunteers, 11-12, Silver Street, London, E.C.

Competition Rider's New Post.

Mr. F. W. Southern, the representative of Messrs. J. Marston, Ltd., and the successful competition rider of Sunbeam machines, has been appointed by the Ministry of Munitions (M.W.S. dept.) at Leicester to take charge of the transport section there. Mr. Southern, who is a well-known motor cyclist, has been manager of the Sunbeam depot for the past two years.

Main Road Impressions.

Probably the most obnoxious man on the road is he who delights in overtaking a low-powered machine and then refusing either to get away or to allow the vanquished one to pass. Sometimes he is out solely on idle pleasure, while the man on the low-powered machine is generally out to get there with as little discomfort as possible, and is in no mood to be impressed by his victor's powers of acceleration.



"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS TANKS. A LETTER OF APPRECIATION WAS SUBSEQUENTLY RECEIVED FROM THE ARMY COUNCIL.

A.C.U. Accounts.

The accounts of the A.C.U. for the year 1916 showed a surplus of £137 15s 1d. on the Revenue Account, which, under present conditions, may be regarded as favourable.

Lightweights in America.

The trend of the motor cycle market in America is illustrated in a recent issue of an American contemporary *Motor Cycling and Bicycling*, by the amount of space devoted to the subject of lightweight machines. Evidently America has wakened to the fact that huge road-eating twins do not represent the sole demand of an educated public, for in the issue referred to eleven new American lightweights, ranging in price from the equivalent to £7 to £36, are illustrated and described. Five of these are more by way of being auxiliary cycle attachments than genuine motor cycles, and, with one or two exceptions, the remainder appear somewhat antiquated and quaint.

Educating the Masses.

But the American public has yet to be educated to the lightweight. To-day, "motor cycle salesmanship usually consists in selling heavyweight machines to people who ask for them," remarks our U.S.A contemporary. "This is bar tender salesmanship. No one ever accused a bar tender of being a salesman. The latest demand is for lightweight machines." This, says *Motor Cycling and Bicycling*, is "latent" demand, as distinct from "positive" demand.

Refund of Taxes Paid.

There is hope that the suggestion in the leading article in our last issue may have effect. In that article we recommended a refund of a proportionate amount of the tax paid in January, seeing that many motor vehicles may stand idle in the summer for want of petrol. A question in the House of Commons last week elicited a reply from the Chancellor of the Exchequer to the effect that the suggestion would be considered. If only the motor organisations would move in the matter *collectively* it is quite probable that a certain allotment of petrol would be forthcoming, or, if that is found impossible, a refund of a portion of the taxes paid.

How Many Motor Cycles?

A contemporary gives the number of motor cycles registered in the United Kingdom as 160,290 in 1916 and 147,904 in 1915. The 1916 figures were made up as follow :

England and Wales ...	131,805
Scotland	19,147
Ireland	9,338

Petrol Restrictions and Road Licences.

It is intimated that the committee of the Automobile Association has asked the Chancellor of the Exchequer to receive a deputation on the matter above named. The principal point is that, whilst loyally accepting the decision of the Government in the present critical conditions, it is considered unreasonable that licence duties should be charged for twelve months for cars which can be used only for four months in the year, and that an equitable adjustment is desired.

Conditions for the Arbuthnot Trophy.

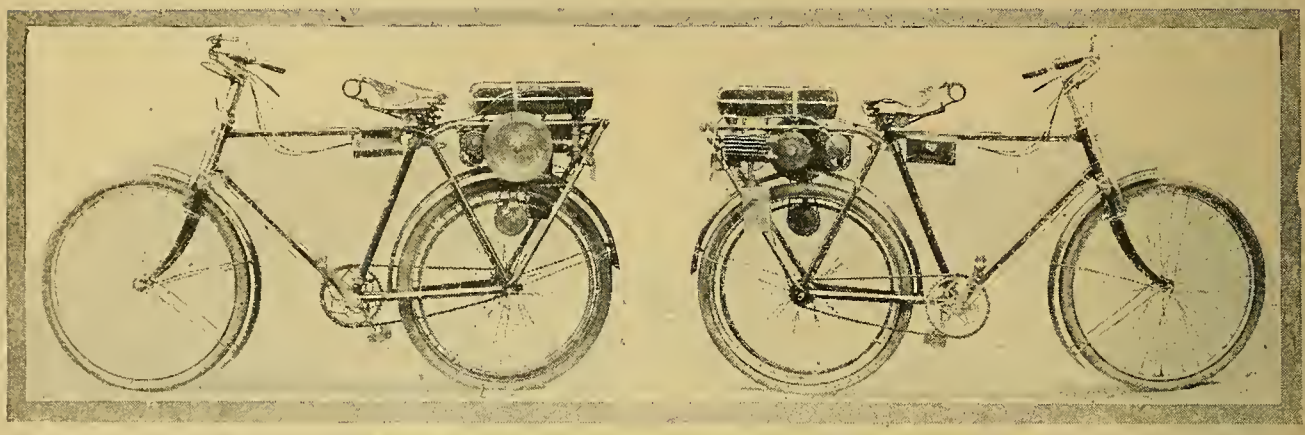
The Competitions Committee of the Auto Cycle Union has decided, in connection with the Arbuthnot Trophy, that under the present conditions it is inadvisable to formulate any definite conditions for the Arbuthnot Trophy Annual Competition. The unexpected balance of the Trophy Fund, amounting approximately to £100, has accordingly been invested in War Loan, to be spent ultimately in the provision of awards. A replica of the trophy is to be presented to H.M.S. *Orion*.

Don't Over-oil.

We find that small two-stroke machines, used only for very short journeys, such as running in and out from business—a matter of two miles at a time—require an absolute minimum of oil. This is due to the fact that the engine never really becomes warmed up, as on a long journey, when not only the cylinder and the piston, but the crank and connecting rod, and indeed the whole interior of the engine, become hot enough to cause evaporation and burning of the lubricant. On short journeys practically no evaporation takes place, and, therefore, the oil feed should be sparingly adjusted. One rider informs us that he has used only a pint of oil in six months' daily riding. This, we think, is running it rather thin; but we find from personal experience that one particular two-stroke requires only about a tablespoonful of oil for every ninety miles, made up of two-mile runs Beware, therefore, of over-oiling.

ANOTHER MOTOR-ASSISTED BICYCLE.

THE ZEPHYR MOTOR ATTACHMENT FOR PEDAL CYCLES.

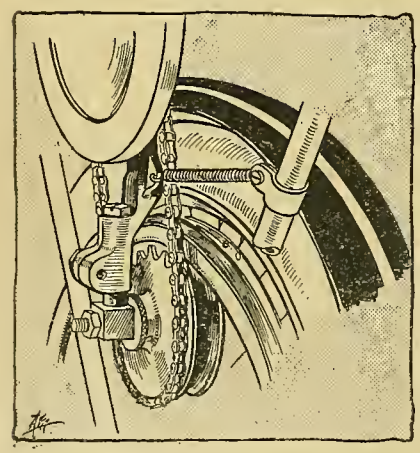


The Zephyr motor attachment fitted to a standard roadster pedal bicycle.

IT was just over a year ago, in the issue of November 18th, 1915, page 489, that we described an attachment handled by the London and Westminster Industrial Syndicate, Ltd., 8, Victoria Street, London, S.W., designed to fit to the rear of an ordinary pedal cycle. In this article full details of the preliminary model were given.

Since that date, owing to the war, the Syndicate, of course, has had no opportunity of making any arrangements with regard to the selling of the device; but, from the mechanical point of view, it has not been idle, and has now brought out an improved model.

The attachment, which now bears the name of the Zephyr, consists of a two-stroke, single-cylinder engine, carried horizontally on a special form of carrier attached to the rear of the cycle. This carrier resembles, to some extent, an ordinary luggage grid; but, whereas the preliminary model had the engine bolted to a platform which was bolted in turn to the carrier, the new model has been considerably simplified in design, the engine being bolted direct to the carrier itself.



The Zephyr transmission, demonstrating the method of carrying the friction wheel on the rocking arm.

How the Engine is Attached.

This carrier consists merely of two parallel tubes attached to a lug clipped round the top of the seat tube of the bicycle. It is strengthened by means of transverse members or brackets, which take the form of clips, and serve to join the two horizontal and parallel members. The cylinder head casting is made in such a form that it is bolted on to one of these brackets, while another of the brackets serves as a support for the crank case. These brackets are also used as an attachment for the petrol tank, which is carried on the top of the carrier, and will be lower in the final model than is shown in the accompanying photograph.

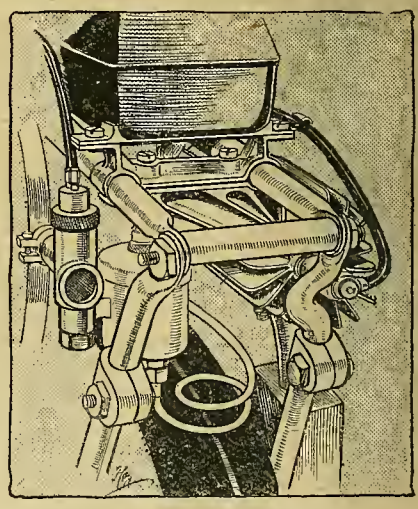
The engine has a bore and stroke of 51 mm. × 51 mm. It does not present any very special features except that the transfer port is provided with a neat cover, which can be removed for cleaning purposes. The side of the crank case may also be removed without difficulty. It has not been definitely decided that a two-stroke engine will be adopted finally, and it is quite possible that a four-stroke engine will be fitted to the first models to be manufactured.

On the mainshaft there are two sprockets, one serving to drive the magneto, which is carried in an inverted position at the forward end of the carrier, while from the other a chain runs to the driving pulley. The carrier is supported by long tubes extending to the rear hub of the bicycle, which are made telescopic, so that the whole unit may be raised or lowered if desired.

The Transmission.

The general interest of the machine, however, lies in the transmission, which is effected by means of a sprocket mounted on the engine-shaft, from which a chain runs to another sprocket mounted on an arm, the upper end of which has a phosphor-bronze bearing moving on a steel sleeve fixed over the boss of the crank case. This lower sprocket is mounted on a spindle, on the other end of which there is a fibre wheel engaging with the under side of the belt rim spoked on to the wheel of the bicycle. This sprocket is loose on its spindle, and is secured merely by friction, being held by one fibre ring and two locking rings, so that just sufficient slip is allowed to absorb any abnormal shocks. When the rocking arm hangs down there is no contact between the fibre pulley and the belt rim, consequently this is the free engine position.

The engine is started by pulling the rocking arm forward by means of a Bowden wire on the handle-bar of the bicycle. This causes the friction wheel to come in contact with the belt rim, so that when the back wheel is pedalled the engine is driven through the agency of the friction wheel and chain. As soon, however, as the engine fires, owing to the direction of rotation of the friction wheel, no power is transmitted, the tendency being to disengage itself; but, on the Bowden lever being released, the friction wheel frees itself, and the "take-



Method of attaching the engine and the tank to the carrier.

Another Motor-assisted Bicycle.—

off" spring attached to the arm allows the latter to move towards the rear. As soon as this happens there is a tendency for the friction wheel to run towards the rear of the bicycle against the pulley, and by this means the drive is effected, there being in consequence a certain jamming action which provides just sufficient drive without any danger of slipping.

Some Claims.

The consulting engineer to the Syndicate, Mr. H. B. Molesworth, M.Inst.C.E., one of the editors of "Molesworth's Handbook of Engineering Formulæ," declares that this method of transmission is quite novel, and puts forward several claims in its favour. He points out that when no power is exerted there is no pressure on the contact surfaces, that the necessary pressure is obtained automatically without the use of springs, weights, levers, or other appliances The tangential force causing contact pressure is quite small, and the force required to release contact and free the engine is also quite small, and even this small force can be eliminated by slowing the engine; while, owing to the automatic incidence of pressure on the contact surfaces, any slight inaccuracies of parallelism, or in the truth of the driving rim, cause corresponding adjustments of the mechanism, thus obviating all shocks and wear which would be unavoidable in any other method of transmission.

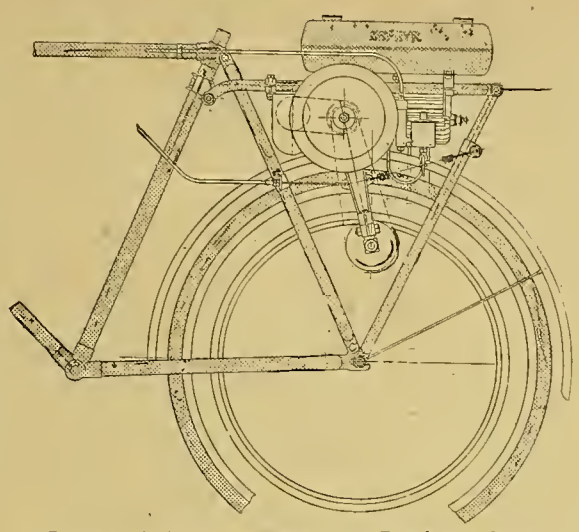


Diagram of the motor equipment. Details are shown of the transmission system and manner of attaching carrier to seat tube.

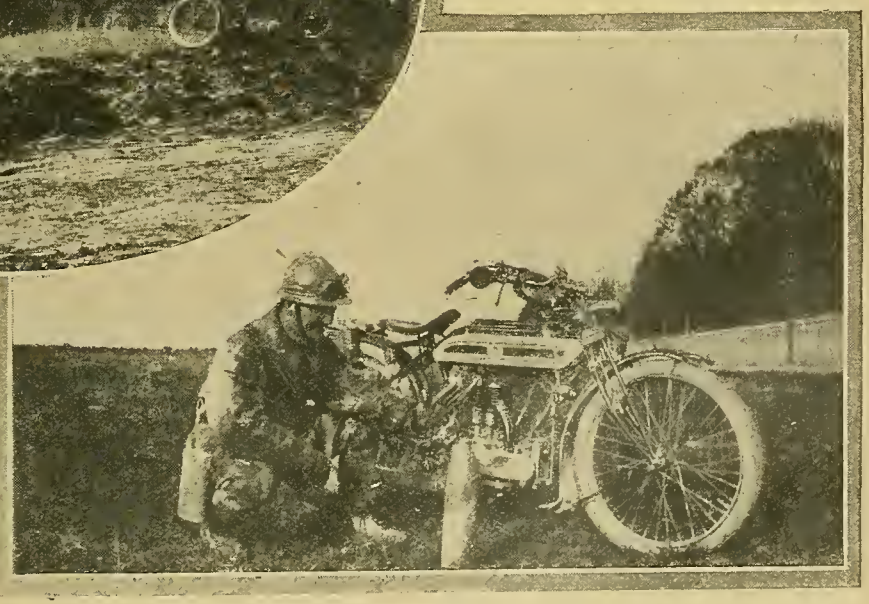
It must be distinctly understood that the "take-off" spring to which we have referred has no other function than to pull against the Bowden wire, the drive being effected entirely by the "rolling-in" action of which we have already made mention, and which takes place as soon as there is sufficient contact between the surfaces.

We have had opportunities of driving both the two-stroke and four-stroke models; but, unfortunately, circumstances prevented us from taking an extended run, which is a pleasure to which we shall look forward at no very distant date.

The Zephyr all on weighs 60 lb., the weight of the unit being 40 lb. Undoubtedly, when the war is over, an attachment of this kind will do much missionary work in converting the pedal cyclist from his humanly-propelled mount to one which is mechanically propelled. Naturally, at the present time it is impossible to get the attachment manufactured, but we understand that arrangements will be made to manufacture in quantities as soon as circumstances permit.

LIGHT CAR MATTERS.

AMONG the leading features of yesterday's issue of our sister journal, *The Light Car*, is an article, "Forty Thousand Miles on a Light Car," written by a leading competition rider now in the Royal Flying Corps. In this article many useful hints are embodied. "Suggestions in Chassis Design," "The Word Fuselage" (describing the derivation of the term), "Red Cross Work in the Midlands," "A Winter's Drive," are among other features included in an attractive issue.



WITH A DESPATCH RIDER ON THE FRENCH FRONT.

(Top) A good idea of the size of big shell holes will be gathered from the photograph, which also depicts the shocking roads the despatch riders have to traverse.

(Bottom) A despatch rider in the Champagne sector and an unexploded Hun shell. It will be noticed that the motor cycle is an ordinary standard model Triumph. (*Passed for publication by the French War Minister.*)

PROTECTING THE BRITISH MOTOR TRADE.

Views of the Association of British Motor and Allied Manufacturers.

CIRCUMSTANCES which may tend to handicap the future of the British motor industry are briefly dealt with in a Memorandum drafted for the information of members of Parliament by the abovenamed association. It is pointed out that a very large number of motor cars and cycles are now in military or naval service, and, presuming that the bulk of these machines will be disposed of at the termination of the war, there is evident danger of markets being flooded and of great difficulty being experienced by manufacturers as regards the disposal of their output of new machines. Owing to special war taxation there will be a shortage of liquid assets available for the extension of trade, while the difficulty of disposing of full output will be aggravated by the fact that motor manufacturers have, in the execution of Government contracts, extended their premises and purchased large quantities of new machinery. For this reason it is essential that home markets be retained and foreign markets be widened and developed so that increased demand can be depended upon.

What to do with Time-expired Machines.

It is pointed out that the British motor industry having been concentrated on Government demands, a great deal of its goodwill has inevitably passed into the hands of foreign competitors. Many firms will not be in a position to resume their normal business after the war till they have had time to reorganise their works, and during that period they will require adequate protection against flooding of their markets, at home and abroad, by foreign competitors.

It is further urged that vehicles no longer required by the War Office and Admiralty should not be pressed for sale or disposed of by public auction, but should be disposed of for use in devastated countries, and the remainder marketed gradually with the assistance of manufacturers and their agents. All vehicles should be overhauled by their manufacturers before sale, and their subsequent condition guaranteed. This would protect the reputation of the manufacturers and the interests of the buying public.

THE QUESTION OF SUBSTITUTES.

PETROL substitutes are available at the moment, and may be used to eke out what petrol remains. There does not seem to be any prospect as yet of there being any restriction placed upon their sale, or any tax being imposed, provided, of course, the quantity imported is not largely increased and the Customs authorities do not demand a tax to be placed upon these fuels. It is certain, at any rate, that the Petrol Control Committee is by no means anxious to place petroleum and white oils on the same basis as petrol.

The reason that pressure has been brought by the Government to bear upon the Petrol Control Committee to issue no more licences after the present petrol tickets have expired is obviously to ensure that there are ample reserves in hand for the use of both the Navy and Army.

Demand and Supply.

The Petrol Committee has, of course, certain figures at its disposal which enable it to gauge the needs of the Services, and also the available tonnage at the country's disposal to bring in the petrol. The Committee knows the amount of petrol due to arrive in Great Britain between the present time and the end of April, and it knows approximately the requirements of the Services. It is aware how much is needed for essential commercial work, and if its calculations are correct there will be no surplus to distribute to private owners—allowing a reasonable margin for safety. In the unlikely event of the import of motor spirit exceeding the amount estimated, there may be a certain balance which could be licensed to the owners of private cars and motor cycles. It would be absolute folly, however, to calculate on this surplus, and we only mention it as being just a bare possibility.

THE A.C.U. IN WARTIME.

A SUMMARY OF THE FOURTEENTH ANNUAL REPORT OF THE YEAR'S WORK.

THE fourteenth annual report of the Auto Cycle Union is one of the best this body has ever produced since its inception, being a wonderful record of valuable war work, while, at the same time, the Union has succeeded in devoting its energies for the benefit of its members in a really useful manner, despite the fact that this is the third time the annual report has been issued during the war.

As regards membership, in 1916 seven hundred members wrote to say they proposed to take advantage of the concession by which members on service may become hon. members, and, notwithstanding the unsatisfactory conditions, the actual value of subscriptions and affiliation fees received exceeded that estimated, and is more than 50% in excess of the corresponding figures five years ago. Several clubs have continued their affiliation to the Union, and there is evidence of increased activity among motor cycle organisations in Overseas dominions.

Recruiting Activities.

The officers of the committee for 1916-17 are those elected for 1915-16, following the precedent set by parliamentary, municipal, and other bodies.

During the first six months of the year the staff were engaged in recruiting for the motor cyclist section of the Royal Engineers. The Secretary's scheme of a Central Office to co-ordinate the work of the various local reserve committees proved invaluable, and gradually became so automatic in its action that it was taken over by the military authorities. Since the Central Office was established in January, 804 recruits were finally passed, while 1,779 applicants were interviewed, and some 3,400 applications by letter were dealt with. The total number of applications for enlistment dealt with by the A.C.U. amounted to 11,579.

Letters of appreciation regarding the work of the A.C.U. were received from the Director of Staff Duties and the Commandant of the Signal Service Training Centre, and from Brigadier-General A. Campbell Geddes, Director of Recruiting. In his letter General Geddes writes:

> "I am directed to tender to you an expression of thanks and appreciation for the patriotic and cordial assistance you have rendered in this direction, and trust that your help will be available at any future date should the necessity arise."

The Proposed Motor Cycle Taxes.

As regards legislation, the proposed taxation of motor cycles in last April called for energetic action on the part of the Union. The matter was dealt with efficiently and promptly. After numerous interviews and correspondence, the A.C.U. suggested an increased tax on petrol, and the committee was of the opinion that the action taken by the Union directly resulted in the abandonment of the increased licence duties and the increased taxation on motor spirit, which, of course, is much fairer.

The National Motor Volunteers.

As regards other war work, the A.C.U. helped to secure the recognition of the National Motor Volunteers through its Secretary, who holds important positions in both the Volunteer Force and Special Constabulary, and the Union is also represented on the Central Committee for Employment of Discharged Soldiers and Sailors connected with the motor industry.

Routes and other Assistance.

The Touring Department has been engaged in dealing with applications for routes made by officers on leave or stationed in this country, and in making the necessary arrangements on behalf of members requiring the import or export of motor cycles and spare parts.

The committee has reason to believe that it will shortly be in a position to announce that the benefits of the R.A.C. "Get you Home" scheme will be extended to members of the A.C.U.

The Legal Department has done much valuable work, and two or three cases are instanced in which the Union was able to help members out of legal difficulties, while a good proportion of cases brought up against motor cyclists have been dismissed when the member has been represented by the A.C.U. solicitor.

Insurance.

Despite the war, the work of the Insurance Department has been very satisfactory. Over five hundred members have this year availed themselves of the concession granted to full policyholders—that is, free touring membership—whilst the valuable arbitration clause in the policy has resulted in three disputes being submitted to the Union for settlement, and satisfactorily concluded.

The A.C.U. Roll of Honour contains many famous names, the chief being that of the late Rear-Admiral Sir R. K. Arbuthnot, Bt., K.C.B., M.V.O. The statuette forming the trophy, founded to perpetuate his name, bears the following simple inscription:

ROBERT KEITH ARBUTHNOT,
Bt., K.C.B., M.V.O.,
Rear Admiral, Royal Navy,
Who died in action on H.M.S. *Defence*
at the battle of Jutland,
31st May, 1916.
A great motor cyclist.

Numerous other names are included in the Union's Roll of Honour; but it has been found impossible to compile a complete list of those members of the Union who have either died serving their King and country, or who have earned well-merited honours and awards in the service of the State.

AVERAGE PRICES.

WE give below the average prices of second-hand models offered for sale in *The Motor Cycle*. Where possible the average for the past week is quoted, otherwise the last average is given, if within four weeks.

NOTICE TO PETROL DEALERS.

UNDER an Order made by the Board of Trade, dated February 6th, 1917, all licensed dealers in motor spirit are notified that they are henceforth required to keep a book in which are entered particulars of all the motor spirit sold by them as follows:

ACCOUNT OF MOTOR SPIRIT SUPPLIED.

Date when Supplied.	Quantity of Motor Spirit Supplied. Gallons.	Name and Address of Purchaser.	No. of Petrol Licence held by Purchaser.*

* Particulars to be taken from the licence.

The book must be kept on the premises, and be open to inspection by any officer of Customs and Excise or by any officer appointed by the Petrol Committee.

Any person failing to comply with the Order is guilty of a summary offence against the Defence of the Realm (Consolidation) Regulations, 1914.

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

PORT DESIGN ON TWO-STROKE ENGINES.

Sir,—I note "Excelsior's" statement that he can climb Sunrising on his Villiers two-stroke geared 5¼ to 1. I should like to say that I am rather doubtful of his performance; in fact, from my experience of two-strokes, I should say the feat is impossible.

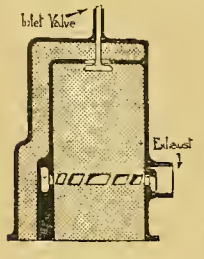
I have at present a Metro. two-stroke, single-geared 5½ to 1, and although it is one of the best I have ridden, and will easily climb such hills as Gorcot and Mucklow, I feel sure it would not get up Sunrising.

Would "Excelsior" ride over to Sunrising with me one of these days? We could have an interesting test of our respective machines in a purely friendly way. Since "Excelsior" also lives in Birmingham, I think this could easily be arranged, and I await his reply with interest.

Edgbaston. METRO. SINGLE-SPEEDER.

Sir,—I think "Progressive's" article on two-stroke engines calls for the following remarks:

Obviously he contradicts himself when he states that one of the advantages of two-stroke engines is "good thermal efficiency," and one of its disadvantages "high petrol consumption." The "brake thermal efficiency" of a good four-stroke engine is 24%, but I should be surprised to hear that on "two-strokes" of the type illustrated more than 17% is attained. My experience is that much better results are obtained on "two-strokes" by having a "straight through scavenge," obtained by placing the inlet valve on the cylinder head and having a ring of exhaust ports, as shown in the accompanying sketch.



A. H. Wilde's suggested port design for two-stroke engines (See letter.)

Of course, this complicates the engine, and makes it more expensive; but I am afraid that only on these lines can "thermal efficiency" be increased.

Regarding "Progressive's" suggestion that the exhaust port area could be increased by increasing the width, I should like to point out that there is a limit to this, as *local* cutting away of the cylinder wall will lead to cylinder distortion on heating. The previous suggestion gives ample area, and the cylinder being cut away symmetrically will not distort.

A. H. WILDE.

HEATING THE INDUCTION PIPE.

Sir,—I have noted with considerable interest the various letters that have appeared recently regarding the improved results obtained when the carburetter is fitted with a suitably arranged hot air supply.

The extreme cold, and the fact that only the heavier grades of fuel are now available, has tended in no small degree to emphasise the necessity of heating the induction system, and especially so in the case of the "flat twin," owing to the length of exposed inlet pipe. Neglect to provide adequate heating of this pipe has led to this type of engine in many instances obtaining an unenviable reputation for consumption and irregularity of running.

It is somewhat strange that what is known to be the best method of carburetter fitting on car engines is usually totally ignored when fitting a carburetter to the engine of a motor cycle, as in numerous instances I have seen carburetters *attached* (not fitted) in such a manner as effectually to preclude any possibility of even reasonable consumption being obtained, and a certainty of their freezing up in average winter weather.

As far back as 1912, in the fitting leaflet supplied with all Everest carburetters, special attention was directed to the necessity of the proper heating of the induction system if maximum results were to be obtained, together with suggestions as to how this may be accomplished, and also the reasons for its necessity.

Mr. G. E. Bradshaw, in your issue of January 25th, also testifies to the "vastly improved" results obtained when this method was adopted, which, doubtless, would also have saved "Ixion" an unpleasant experience. E. P. EVEREST.

BRITISH MAGNETOS.

Sir,—Having read a lot lately *re* magnetos being made in England, I wish other motorists to know of the handsome way one of our English firms has treated me. I ride a 1916 Rudge Multi fitted with a C.A.V. magneto. One day I had to pull up through the engine misfiring. I found the points were badly pitted on the contact breaker. I trimmed them up, and got on all right. I wrote to Messrs. Vandervell at night, explaining the trouble I had had, as I did not think it ought to have been so bad in the time. To my surprise, I received a new magneto by return of post, to use whilst I sent mine to them to overhaul. After a few days I received my magneto back, and, of course, I returned the one they so kindly lent me. They have not charged me a penny.

I must say that if all English firms treat their customers in the same way, there will not be much room for foreign firms after the war. H. J. BLAND.

FORCED INDUCTION FOR FLAT TWINS.

Sir,—Now that the so-called "flat" twin is occupying such a prominent position in motor cycling topics, I would be pleased to see a criticism of the following suggestions:

We know that in two-stroke engines crank case compression is very nearly perfect. Also that automatic valves in the piston heads have been proved successful in the highly efficient aero engines. Why not incorporate these two factors in the opposed twin? Theoretically, I mark these advantages: *(a)* Abolition of two long induction pipes. *(b)* Cooler piston head; therefore, less carbon. *(c)* Gas forced into the cylinders under pressure, *e.g.*, twice the c.c. of one cylinder is reduced into the crank case, and on the inward strokes this gas is forced into one cylinder. In practice, no doubt, only about one and a half times the volume of the c.c. of the cylinder would be injected. *(d)* The present two side by side or overhead valves could both be for exhausts. The advantages here are obvious—both for silencing and rapid scavenging. The valve in the crank case could easily be mechanically operated, although with the powerful induction the automatic would be a success. The piston inlet valves should be more efficient than the side or overhead inlet because a higher lift is possible. The vacuum in the cylinder and speed of the piston tends to raise, and the crank case compression forces open the valve. Then the change of piston direction and cylinder compression tend to close the valve rapidly. Lubrication, housing of cams, etc., and accessibility of inlet valves could easily be solved by a clever designer. The result would then be that, say, a 2¾ h.p. engine would develop more power than the present 3½ h.p.'s. This should more than repay for the slight additional complications.

There is nothing new under the sun, and possibly the above idea has been fully worked out and rejected. However, I have been one of your readers for several years, and do not remember having seen the subject broached.

Wimbledon. C.L.V.C. 2872.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—Allow me, along with R. C. M. Kermode, whose letter appeared in your issue dated February 8th, to express my surprise that there seem to be so few exponents of the big twin for solo riding. To riders who, like myself, appreciate power, speed, and simplicity, the big twin, with direct belt drive and perhaps a good hub clutch, appears ideal. In pre-war days I used to ride such a mount, without a clutch, however, and I was in the habit of riding it with the exceptionally high gear of 3 to 1. Of course, the acceleration was not so good as might be, but never have I been able to produce the slightest knock. It was not at all a racing type of engine, and would commence to fire at a little above walking pace, ticking over in traffic till one could almost "count the revs." The pleasure of riding a big twin solo with a fairly high gear has to be experienced to be realised. Personally, I always like to feel that, however fast I wish to go, and however hilly the country I encounter, I rarely have to push the engine beyond 75% of its full power. I do not think I can be accused of being a "road hog," yet the knowledge that, go as fast as I can, I shall still have two or three horse-power to spare is very pleasant to me. To the real motor cyclist, the knowledge that his mount is "all out" has few attractions. Even if one rarely has to use it, it is comforting to feel on a long, hilly run that one has plenty of reserve power and is not pressing the engine unduly. It was always my boast that I could generally bear my hand on the cylinders at the end of a run. Why not have as much power as one can get, provided one can get a reasonable petrol consumption and medium weight (which generally go together), also a certain amount of tractability? The machine I rode combined these essentials, and I do not consider it in any way exceptional. Eighty to eighty-five miles per gallon I could obtain any time, owing probably to the high gear, whilst I could travel at practically any speed the road would allow, and this without the slightest sensation of effort or vibration. Neither is a mount of this type necessarily at all heavy.

Of course, this machine would not suit any rider, but to one who, like myself, has not reached the age when thoughts turn to touring bars, four-speed gear boxes, and family sidecars, and who does not mind a bit of inconvenience in thick traffic, the extreme simplicity, reliability, and power of such a machine appeal strongly. I rode my 8 h.p. solo some thousands of miles, and of all the other bicycles I have had none gave me such pleasure in riding, so little trouble, and so little expense of upkeep. Like one of your former correspondents, "I dream of a powerful twin and smooth straight roads." (Pte.) FRANK L. SHIELD.

Sir,—The lively controversy anent the respective merits of the single and flat twin is surely the most interesting and educative argument that we eager readers week by week have been privileged to enter into since the very early days of motor cycling. So far, the single enthusiasts do not fear the foreshadowed doom of a tried, proved, and trusted friend, but as in turn each owner is tempted to try the delights of the flat twin the manufacturers will require to turn out the 180° type in ever increasing numbers. The pros and cons have been threshed out so well that perhaps my own experience may seem flatter than anything, twin or no twin, but a year's mileage of 6,000 on a 2¾ h.p. Douglas, requiring no renewals except two sparking plugs, valve springs which did not break but lost temper, and retreading of back cover, is surely convincing. The transmission is in perfect condition, and though when last I had the engine down the big ends had the least shade of play, all other bearings and piston rings were in capital order. I found that the fitting of a long exhaust extension 1in. pipe not only improved the tune, but the tone also; effect—the song of the Gnome. Combining pleasure with training at High Wycombe, I straddled the tank at the end of each week, and over a very difficult course reached home at Enfield in never less than one and a half hours, which included the climbing of Amersham hill with its bad "take off." One outstanding run, Enfield to Hitchin, twenty-five miles, with flapper bracket occupied, in fifty-two minutes. Not much at first glance, but really good when I mention the machine is single-geared, and has never once been driven all out. My view of the position is perhaps a narrow one, but the type of power unit which made the reputation of the finest lightweight existent can and will be developed to take in practically all machines, except where intended for exceptionally heavy sidecar work, in which class the miniature "four" designed on car lines has the better field. I feel sure that most of the single devotees will succumb to a general preference for the flat twin once they take it to their hearts. In spite of all restrictions *The Motor Cycle* retains its old standard, and my pals, who once knew not the difference between a magneto and a mudguard, now command me to help them obtain a "'bus" of some sort when the open road (and hairpin corners) await us all once more. Usual disclaimer. GNR. J. CHESHER.
B.E.F., France.

AN APPEAL FROM THE FRONT.

Sir,—It is with the utmost pleasure that I look forward to receiving my copy of *The Motor Cycle* each week, as there is always contained therein some topic to interest every class of motor cyclist.

With reference to the "Single *v.* Flat Twin" controversy, may I be permitted to state my opinion. I favour the single-cylinder, as from fifteen months' experience out here with both types I find the single much easier to keep in tune than the (may I call it its rival?) flat twin. Decarbonisation and the grinding in of valves is to most motor cyclists a bugbear, but with the single-cylinder it is not a long job. Mudguarding still needs more thoughtful consideration than it has received up to the present. Motor cyclists soon become coated with mud out here simply through the lack of mudguards of ample proportions. In wet weather one's motor cycle and person are simply smothered in mud, and in weather when the mud is tacky the clearance proves to be insufficient, in consequence of which both wheels soon become clogged. I notice that the new Matchless has both its valves enclosed, and I only hope that other manufacturers will do likewise. The motor cycle (a well-known make) which I am riding at present was called upon almost to wallow in mud when I was stationed at Combles, and I soon found the absolute necessity for protection for my valves, both of which would persist in sticking, owing to the adverse conditions.

When are we to receive a really weatherproof magneto? I have more than once experienced the same discomfort as "Ixion" with regard to the aluminium plates warping; and, as a matter of fact, the motor cycle I am now riding is fitted with a magneto having the self-same faults. Plugs are also far from faultless, as even under a moderate gruelling they soon pre-ignite. The bearings in the steering head are inadequate for the strain they are called upon to bear, and I only hope that manufacturers will soon realise this fact. Tool-bags are apparently a useless addition to the machine, and soon rattle loose, and are not long in falling off. For this reason our workshop does not fit them now, and so all tools and spares are carried in a haversack. There is barely sufficient ground clearance on many present-day machines, and too often does my crank case hit the ground. However, with all its defects, the motor cycle of the present day is a marvel, and does its work thoroughly and well.

I have noticed that many D.R.'s have transferred their affections to horses; but, personally, I would sooner my machine encounter adverse conditions, and so find its faults, than avail myself of other means of transit.

I will now conclude by wishing your paper, and motor cycling in general, the best of luck. F. BRIGGS.
B.E.F.

A HOME-MADE KICK-STARTER.

Sir,—Your correspondent from South Africa who desired information as to a simple means of providing a 1912 6 h.p. Zenith with a kick-starter will not, I am afraid, be able to utilise the ingenious method outlined by "Kicker" in *The Motor Cycle* for February 1st. In the first place, the 1912 6 h.p. Zenith has the magneto driven by chain; at any rate, any 1912 model that I have seen is so fitted. Consequently, the intermediate wheel next to the magneto which "Kicker" first experimented with is not on the 6 h.p. model, so he would require to change his plans a little to fit his home-made kick-starter to a 6 h.p. model. In the second place, it would require a skilled mechanic who could use a lathe to undertake the making of "Kicker's" starter.

I have also been trying to fit a kick-starter to a 6 h.p. Zenith, and although my efforts have not as yet been a complete success, still I hope, with a few more alterations, to possess a serviceable one. The free engine that can be obtained by lowering the Gradua gear does not possess the advantages of

a hub or countershaft clutch; and besides, if used constantly as a clutch for starting and in traffic it would wear out rubber belts in no time. Being aware of this, I obtained a second-hand clutch hub. I got a new spindle made for the hub to fit the chain stays of the Zenith. I fitted the clutch pedal to the slotted plate No. 1 (known to all Zenith riders), so that the movement of the back wheel would not interfere with the clutch adjustment.

Some weeks ago there appeared in *The Motor Cycle* a simple kick starter for Triumphs and other pedal machines. I used the tip, which got me easily over the difficulty of starting with a kick. The machine is now equal to a 1916 model. The clutch hub allows starting from the saddle, and all traffic dangers are things of the past. I have not yet fitted the rear brake, as it will require to be fitted to the right side, or else work inside the groove of the belt pulley. If any one could give me any hints as to fitting the brake, and also tell me if it would be possible to fit hand control to the clutch I would be much obliged. BOSCH.

Eglinton, Co. Derry.

VALVES AND EFFICIENCY.

Sir,—I am quite in accord with "LK 1810" that overhead valves are by no means the last words in engine efficiency. I also have a 1914 3½ h.p. Premier fitted with extra exhaust ports, and a heavy C.B. sidecar attached, and it has not yet failed me nor jibbed at any hill. With the exception of a new back cover and belt, the machine is still the same as when it left the Premier factory, being still "good looking" and equal to new.

I am not interested in records, but have followed closely all reliability trials and the T.T. races. At present I am closely watching the development of the flat twin.

Llanwrtyd Wells. D.C.W.

WHO SHOULD HOLD DRIVING LICENCES?

Sir,—Your correspondent, Mr. Esnouf, asks if I have never heard of cases in which both parties swear that they blew their horns but neither heard the other. Certainly. There are plenty of such cases, but, fortunately, there are also far more cases in which a horn *is* heard and a collision avoided. Has your correspondent never met with a cross road which cannot be seen when travelling on the main road on account of high hedges or buildings, etc.? If a car is travelling along the main road and another is travelling along a cross road at such a time that they will meet at the same spot, it ought to be obvious to anyone of average intelligence that there *must* be a collision if the driver in the cross road blows his horn and it is not heard by the driver in the main road. By sheer good luck, a deaf driver may avoid accidents for some years—so might a nearly blind driver—but neither should be allowed in the driver's seat. As to runaway horses, there have been several cases in my neighbourhood within the last two years.

M. HITCHCOCK.

STARTING ON ACETYLENE.

Sir,—There has been much talk in these columns recently on the fearful dangers of using acetylene gas for motor cycle engines. We are warned that if we use it we are likely to get blown off the earth, or something dreadful, but has anybody ever thoroughly "tried out" its possibilities? As far as I can make out, the only people who have ever tried it at all are those who have taken their lamp generators and just fixed the tube into the carburetter orifice or the induction pipe, turned on the water, and then started their engine, never worrying about how much gas they are giving it, with the result that they have given it enough to blow the cylinder off. This is hardly a scientific way of testing it.

Is it necessary to give the engine such a violent charge? Cannot it be diluted with air, or given in a small enough quantity to get the right explosive pressure, if it cannot be diluted? We could have a smaller combustion space.

I should imagine that the generator necessary for an ordinary motor cycle engine would be much smaller than the present petrol tanks, and would probably be much cheaper to run on than petrol; also your gas would not depend on the suction of the piston for its production.

I have never used acetylene for any purpose other than lamps, but now that petrol is "off" we have got to find something else or go without, and the substitutes at present on the market appear to be a good way behind petrol for general efficiency and facility of use.

Can anybody give a decisive reason why acetylene cannot be used? The mere fact that it is a much more violent explosive than petrol gas is hardly sufficient.

K. V. CHIDLEY.

Sir,—Just a few words, with your kind permission, on the letter in your last issue from the British Acetylene and Welding Association.

To begin with, its general character leaves something to be desired from the point of view of the generally courteous character of "controversies" in your paper.

I am not concerned to vindicate any claim I made to knowledge. It is backed by quite substantial guarantees from our highest institutions.

The letter you published last week from one who had tried acetylene, curiously enough, gave as one main reason for dropping it the probability of the cylinder being blown off, so I appear to have the practical experience of motor cyclists to back me in the matter of a warning which was admittedly made on general scientific grounds.

Mr. Lucas is "at a loss to know what object" I had in writing. My object was the safety of my fellow motor cyclists. Let me remind you I did not question the results said to be obtained, and stated that in so many words, as also that I knew it had been tried with varying success in different forms of internal combustion engines.

Might I ask what object the secretary of an acetylene commercial association has in his somewhat unnecessarily severe attack on an unknown correspondent, with his direct and derogatory personal statements?

I assume that Mr. Lucas knows (as I know) the practical method of acetylene welding, and the very large use to which the oxy-acetylene flame is put, not only in Government dockyards, but in most garages where repairing is done to any extent. If he knows, his knowledge tells him that the two gases are kept in separate containers, and that in the usual "blow through" jet it is a scientific inaccuracy to speak of the gases being mixed in anything like the way in which the expression "mixing" describes the condition in the cylinder of an engine, the real fact being that a jet of pure acetylene burns in a surrounding envelope of oxygen; or (according as you look at it) a jet of oxygen burns in a surrounding envelope of acetylene. There is no mixture before combustion.

Even if a "mixed jet" be employed, Mr. Lucas must know that a very small chamber indeed is supplied in which the two gases may become mixed, and that the employment of such a jet requires far more skill; that the accurate balancing of the mixture is one which requires control valves to guard against oxygen being forced into the acetylene container, or *vice versa* by way of the said very small chamber; in fact, that a "mixed jet" is decidedly one which would never be put into the hands of anyone but an expert, whilst a "blow through" as usually employed may be worked by any person of average intelligence. The quoting of acetylene blow flames as evidence of unrestricted mixing of oxygen and acetylene in actual practice is, in fact, a bit of "special pleading" that has no bearing at all on the question of internal combustion engines; otherwise, will Mr. Lucas recommend us to use the same materials in engines as blow-pipes, *i.e.*, pure oxygen and acetylene, with perfect confidence in the continued existence of our engines, not to say ourselves? For the calorific value would be enormous. Please note, I ask the above question to be answered without any side issues as to expense.

Mr. Lucas ridicules my statement as to there being a law against making a mixture of acetylene and oxygen in the sense any ordinary person would attach to "making a mixture." Will he kindly call at the office of the Board of Trade and obtain confirmation of his view? If he does so I will admit that I misread a statement in the public press some time ago.

One last point. Mr. Lucas speaks of certain engines in use in country houses, etc. (he speaks, indeed, of hundreds), successfully using acetylene: has he thought of the very great difference in the strength of an ordinary gas engine cylinder and the light casting of a motor cycle engine?

He asks me to state my "fatal" accident instance. I stated in my original letter where an account of it could be found. F. C. LEES, M.A. Oxon.

THE ISOCHRONOUS SPEEDOMETER.

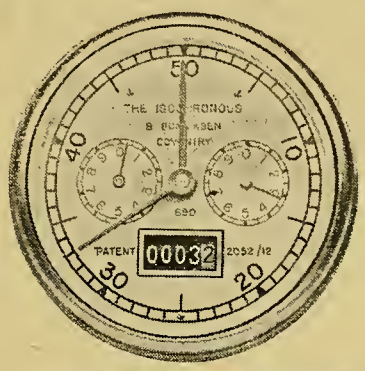
An Instrument Designed on the Principle of Equal Intervals of Time.

IN its action the Bonniksen speedometer is the most original and ingenious instrument of its kind. It is produced in Coventry at the Norfolk Street Works of Mr. B. Bonniksen, and the inventor is in the happy position of being able to make delivery in a reasonably quick time, which will interest those who have necessity to check their mileage. During a recent visit to the works we were shown the inventor's tackle for demonstrating the working of the speedometer, and the internal mechanism was also exposed for our inspection. Some time ago we described the instrument in *The Motor Cycle*, and have previously referred to the excellent finish of the parts.

Probably the two points which will appeal most strongly to the ordinary rider are, firstly, that the speed indicating hand is absolutely steady, indicating the reading without fluctuation, and so enabling the speed to be read accurately, no matter how fast the machine be travelling or how bumpy the road. The second point is that, although only calibrated to 50 m.p.h., speeds can be recorded up to 100 m.p.h. or more.

How the Speed is Indicated.

The dial, which is 3in. in diameter, is calibrated from 5 to 50 m.p.h. Two hands are used in this instrument, and working alternatively one indicates the speed for a period of exactly five seconds, when it returns to zero, the second hand having in the meantime taken up a position to give the reading. Thus the speed indicating hand remains rigidly in position for five seconds, and any acceleration or deceleration is not shown till the other hand comes into operation—the reading, therefore, being given in corrections at five seconds intervals. With the aid of this information those riders who are mathematically inclined are able, by means of a table provided by the makers, to calculate the available horse-power of their machines at certain speeds.



The Bonniksen Isochronous Speedometer. The two small dials register the trip mileage up to 100.

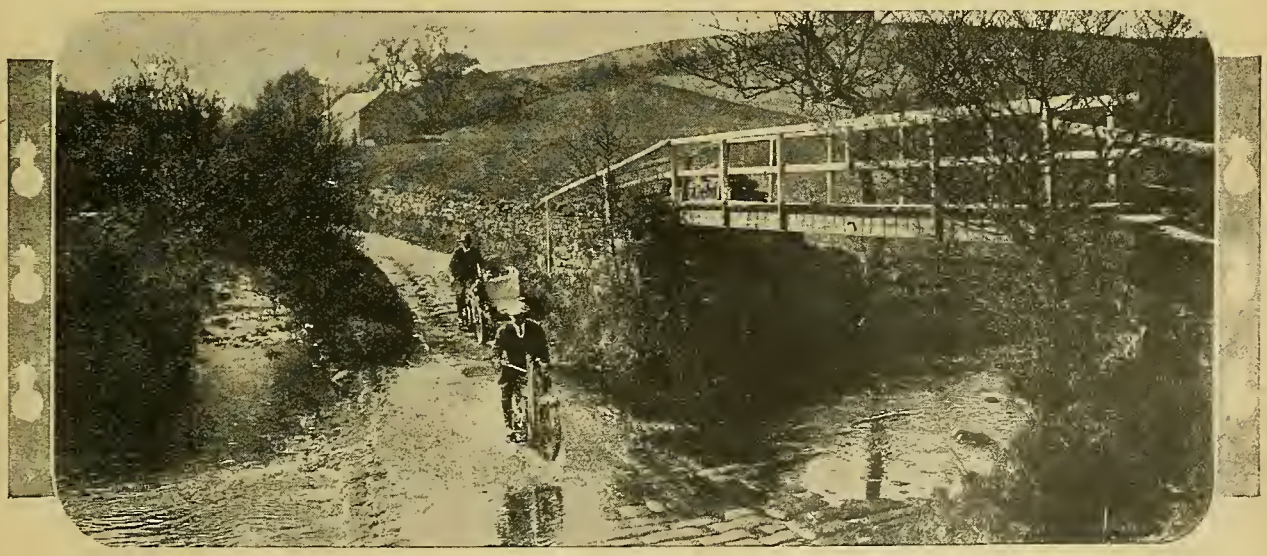
The Principle of Working.

Practically all speedometers are governed by centrifugal governors, though some are magnetically controlled. The Isochronous, however, is controlled in the same manner as the hands of a watch, viz., by means of a balance wheel and spring. In the Isochronous the distance is registered by the indicator hand, which is geared direct to the road wheels by a flexible shaft, while the time is accurately controlled by the watch mechanism. The watch escapement wheel is driven by means of a tiny friction clutch, which takes the place of the main spring of a watch, and causes the balance wheel to oscillate, giving exactly two oscillations in half a second, irrespective of the machine's speed.

The watch mechanism operates a simple device for locking and releasing the indicator hands alternately at five second intervals. The working is as follows: With the machine travelling at, say, 20 m.p.h., No. 1 hand, being released, travels round the dial at a certain speed, which is decided by the speed of the road wheels. When the hand has moved for half a second and gained the 20 m.p.h. reading on the dial, the locking device comes into action and stops the movement of the hand, keeping it rigidly fixed in that position for exactly five seconds, after which it is released and travels on to the zero point ready for a fresh start. The movement of the second hand is exactly similar, and the two come into operation alternatively, so that there is always one hand indicating the reading, while the other remains idly at zero. In other words, the hands operate in turn, each indicating for five seconds, at the end of which space it flies back to zero and the other takes its place. When speeds above 50 m.p.h. are to be recorded, the indicating hand travels one complete circuit of the dial, and gives the reading above the 50 m.p.h. mark; thus 60 m.p.h. would be indicated by one complete revolution of the needle and a reading of 10.

A Time Tested Principle.

The reliability and accuracy of the watch movement is so universally admitted that it is quite unnecessary to enlarge upon it here, and our personal experience with this interesting speedometer goes to prove the absolute reliability of its mechanism and accuracy of reading. The Isochronous speedometer is supplied in several patterns suitable for all types of vehicles, and also with total and trip mileage recorders incorporated. The one illustrated is of this pattern, the right-hand dial recording up to 10 miles, the left-hand dial recording from 10 to 100 miles.



NECESSITY KNOWS NO LAW.

In many parts of Yorkshire the only method of crossing streams with a motor cycle is by fording. A narrow footbridge only is provided. The splash shown above, having a stone foundation, is certainly an improvement on a mud bottom.

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Valve Timing.

My 5-6 h.p. Antoine has automatic inlet valves, and I want to make them mechanical (3in. bore, 3in. stroke). (1.) What is correct for inlet and exhaust open and close on piston stroke? (2.) Should inlet cam have same lift as exhaust? (3.) Should a V twin be perfectly balanced.—J.H.

(1.) The inlet valve should open just after the piston has commenced to descend on the suction stroke, and remain open while the flywheel turns through 190°. The exhaust should open when the piston is half an inch from the bottom of the firing stroke, and close as the inlet opens. (2.) Approximately so. (3.) A V twin cannot be perfectly balanced, but if the cylinders are at an angle of 90° it can be very well balanced.

Worn Belt Pulley.

My motor cycle is a 2¼ h.p. lightweight, fitted with a variable pulley and ⅝in. belt. I am always troubled with bad belt-slip, even with a ¾in. belt, both on bottom and higher gears, though the trouble is, of course, more acute in wet weather.—F.H.D.

It is probable your belt pulleys are out of line, or the pulleys cut to the wrong angle. We should recommend you to use a new ⅝in. belt and a new engine pulley, and take great care to see that everything is in line, and that the pulleys are made to the correct angle, viz., 28°.

Petrol Substitutes and Starting.

I had intended going in for a motor cycle to do my parcel delivery, etc., to cope with increasing trade and lack of hands, and seeing the paragraph in "Current Chat" last week that substitutes for petrol were available, I should be pleased to have your opinion on Kempol, whether this will start the engine without any use of petrol, and if not, what would it be necessary to do to have the engine start entirely on the substitute?—W.M.J.

We believe Kempol to be a very good substitute, but it is doubtful whether you could rely upon it for starting without an injection of some lighter spirit. If boiling water be poured over the induction pipe after flooding the carburetter, so as thoroughly to heat it, some engines will start right away on a heavy fuel, but boiling water is not always available. You would probably be able to start up after an injection of methylated ether, but you would not require more than, say, one pint of petrol a week if you used it only for starting purposes. We have found practically all the well-known substitutes to answer satisfactorily, provided an efficient hot air intake be fitted, but invariably an injection of petrol proved necessary for starting up from cold. If you could obtain a small quantity of methylated ether for injecting through the compression taps for starting you would probably be able to manage, as when once the engine was warmed up you would experience no difficulty in effecting a restart.

Starting on Acetylene.

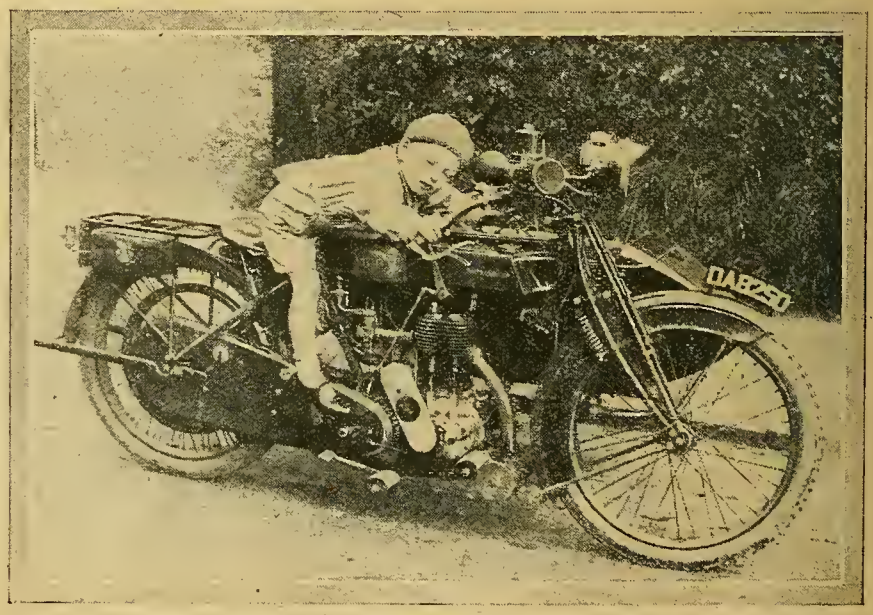
I have a 1912 2¾ h.p. Douglas. (1.) Could this be started on acetylene and run on Petrofin? (2.) How is the carburetter (Douglas) arranged to take both acetylene and Petrofin?—G.E.S.

(1.) The carburetter should have a hot air pipe leading from the cylinder fins to the fixed air inlet. The early pattern of this make of carburetter was not fitted with one, but any cycle mechanic would fit one up for you. (2.) As regards starting on acetylene, opinions as to the advisability of using this are exceedingly divergent. Some people have used acetylene with success for some years, while others have had accidents, suffering from broken connecting rods and even burst cylinders. The acetylene is introduced through a small tube fitted in the inlet pipe. The petrol substitute referred to has been praised by readers.

No Power at Slow Speeds.

I have just acquired a 1916 3½ h.p. machine. This develops exceptional power so long as the revolutions are kept up, but there is none of that hard pulling at slow speeds so generally advanced in favour of the single, and especially the long stroke single. On a slope, as soon as the revolutions drop to a certain point the engine "konks" badly. Also, when ascending a hill with sidecar at moderate speeds when the throttle is fully opened, the carburetter invariably chokes. The magneto has plenty of range for retardation, and the engine bearings are in perfect condition. I shall be much obliged for your advice. —E.D.M.

The trouble may be due to lack of compression, owing to the valves requiring to be ground in, to the machine being geared too highly, or possibly to the bad petrol obtainable at the present time, certain brands of which are very prone to cause knocking. Be careful not to drive on too weak a mixture.



The "Sunbeam" and the "son." A pleasing picture of Mr. T. Blyth Clayton's little three-year-old, who is already a very keen rider—in the sidecar.

Starting in Cold Weather.

I have just purchased a 1915 single-cylinder fitted with a two-speed gear. In cold weather it is very hard to start. Can you help me?—S.B.

To start easily in cold weather flood the carburetter and inject a little petrol into the cylinder. Do not open the throttle too wide, but close the air. If the machine is very refractory at starting take out one of the sparking plugs, turn it upside down, and fill the cup with petrol, then screw it quickly into the engine and attempt to start.

Licences.

Could you please inform me as to the rules governing the licensing of motor cycles? I am told that, as I do not intend using my outfit this year for various reasons, I am not obliged to pay the licence, but that there are certain rules to which I must conform, one of which is that the motor cycle must not be in running order. Also, if the motor cycle is not licensed, is that any drawback to selling?—D.T.

If you have not used your machine this year you are not called upon to pay any licences whatever, but should it be taken out once and ridden by anyone you become liable for the payment of the Inland Revenue tax. There is no rule to the effect that the machine must not be in running order. The only way in which the fact that the machine is not licensed could possibly affect your chance of selling is that you would not be in a position to give your prospective purchaser a trial run.

Carburetter Adjustment.

My machine is a 2½ h.p. four-stroke fitted with a B. and B. carburetter which has a No. 35 jet. Is this too large? When running I cannot give full air unless the throttle is nearly fully open. Does one consume as much petrol when running slowly as fast? I have only just bought this machine, and upon applying for the transfer of ownership I am informed that I must reregister it to continue to use the present number, because I am told the registration was cancelled last February. The dealer I bought the machine from denies that he cancelled the registration. Could the previous owner have done so? I thought it was only necessary to reregister if the number is to be altered.—V.A.B.

The jet certainly seems to be on the large side, unless the carburetter is one of those which has a movable needle in the jet; but what you say about the air adjustment of your machine seems to indicate that the carburetter is quite correctly adjusted. You should only be able to give full air when the throttle is open fully. The least petrol is consumed when running at about twenty miles an hour, and the most when running absolutely "all out." Yes, the previous owner may quite well have cancelled the registration of the machine you have bought. Under the circumstances you will have to register the machine afresh, paying five shillings.

Fixing Platinum Points.

The platinum points of my magneto are about worn out. I have platinum suitable for the job, but would like to be sure that the points are riveted on or otherwise securely fixed. I have used platinum for various electrical instruments, and have soldered it on the former, but the platinum points were only very small.—N.J.

Platinum points are either silver soldered or electrically welded into the rivets. Soft soldering will not do.

Difficult Starting.

My motor cycle will not start unless I inject petrol into the cylinder. I have also to have the spark well advanced before I am able to start. Could you tell me the reason and the remedy for this?—I.G.

There is nothing extraordinary in your having to inject petrol during the cold weather, and also in having to advance the spark for starting. Most machines require these preliminaries. After starting you might retard the spark a little if you find that this permits the engine to run more evenly. If the engine backfires when the spark is fully advanced, you might set the magneto timing a shade further retarded.

READERS' REPLIES.

Misfiring.

Re the "misfiring" troubling "T.B." (February 1st.) I was troubled with the identical symptoms on my Rudge Multi, also fitted with Ruthardt magneto, and found that the bearing of the fibre wheel in the contact breaker had worn oval, so that by every sixth revolution it came to the part out of the centre, thereby not opening the points on that stroke. A new fibre wheel should overcome the trouble, or if that is unprocurable the bearing of the present one may have a bearing inserted centrally and go on again quite satisfactorily. The above may also interest "F.W.R." (January 25th), who seems to be suffering from the same trouble. Probably being a two-stroke engine would explain why it misses at the twelfth explosion, whereas with "T.B." it is the sixth, as it also was with mine.—W. J. Wilkinson.

Tuning a Scott.

May I be allowed to add to your reply to "G.G." on the above subject? He does not say what carburetter is fitted. If it is a Scott carburetter, he might see that the air valve on the end of the carburetter is functioning properly. I had a similar experience with mine, which proved to be caused by the air valve being rusted up, so that it would not open with the suction of the engine. Consequently it used an excessive amount of petrol. Secondly, dismantle the pepper-box silencer on the end of the exhaust pipe, and see the holes are free. It may not be this, as chokage here only causes loss of power through the inability of the incoming charge to drive out the exhaust. Still, it is one of the points that want attention, and will take off more power than dirty gauzes. I have never had any bother with them. I quite agree with you regarding the necessity for care in the making of the joints, but any slight leak round the holding-down bolt pins is negligible, if the pins are properly tapped home, as there is no compression at the point. I do not agree that Scotts do not pull well after being decarbonised; this has not been my experience; but I never chip out the carbon under the rings of any internal combustion engine. I look upon that as so much packing to prevent leakage. Of course, the rings must be free in their grooves, but if one considers for a moment, there can never be so much carbon accumulate under the rings as to cause them to jam in the cylinder; it can only fill up any space there may be, and so form packing. I have just decarbonised mine, and on the very first run it has never pulled better. See that the pistons are oiled before putting on the cylinders. I do this with a brush, using a mixture of petrol and oil; the petrol evaporates, and leaves a thin even coating on the piston and in the cylinders. Only oil the cylinders about one-third to one-half the way up, or there will be too much when the rings have pushed it up to the end of the stroke. I agree with you regarding the suitability of the Scott for long journeys with side-car. They consume rather more petrol than some, but mere petrol consumption is not everything. I find it very easy on tyres, due to the steady torque no doubt.—D. G. Taylor.

DELAYS IN POSTAL DELIVERIES.

In view of depleted staffs, the curtailment of railway services, and the consequent delay in delivery of mails, readers will greatly assist by forwarding communications (including advertisements) as much as possible in advance of the dates of the issues for which they are intended.

RECOMMENDED ROUTES.

Grantham to Rochdale.—W.R.D.

Grantham, Newark, Southwell, Mansfield, Chesterfield, Baslow, Chapel-en-le-Frith, Hayfield, Glossop, Ashton, Oldham, Rochdale.

Farnborough to Dartford.—R.C.

Farnborough, Ash, Tongham, Normandy, Guildford, Shere, Dorking, Reigate, Redhill, Godstone, Westerham, Riverhead, Shoreham, Eynsford, Sutton-at-Hone, Dartford. Approximately 65 miles.

London (Tally-ho Corner) to Boroughbridge.—J.W.R.

From Tally-ho Corner the route is absolutely direct *via* the Great North Road, which you follow through Barnet, Hatfield, Welwyn, Stevenage, Baldock, Biggleswade, Eaton Socon, Buckden, Alconbury Hill, Norman Cross, Wansford, Stamford, Grantham, Newark, Retford, Tuxford, Bawtry, Doncaster, Ferrybridge, Aberford, Wetherby, Boroughbridge. Approximately 210 miles.

Agricastrol.

In view of the great possibilities of agricultural motors, Messrs. C. C. Wakefield and Co. have introduced a special oil for this class of work under the name of Agricastrol motor oil.

Foot Pumps Advanced in Price.

The Wood-Milne Co., Ltd., ask us to state that, owing to increasingly high prices of raw materials and labour, their patent foot pump has been advanced in price 10%.

Motor Cycle Horns.

Those motor cyclists who object to the piercing shriek of the mechanical hooter would do well to peruse the A.M.C. list of electric motor horns. Type F is a useful model for motor cycles, and can be used with the Flash four and a half volt dry cell battery. The address is Apollo Works, Moseley St., Birmingham.

Armstrong Tricycles.

Our readers may remember the Armstrong motor tricycle—a rather unconventional form of three-wheeler made by Messrs. Armstrong and Co., 72, Goldhawk Road, Shepherd's Bush, W., which was described in the issue of *The Motor Cycle* for February 18th, 1915. We are asked to state that during the period of the war the makers find it impossible to turn out any of these tricycles.

Watford Speedometers.

The old-established firm of Nicole, Nielsen, and Co., Ltd., 14, Soho Square, London, and Watford, will in future trade as North and Sons, Ltd. The original business was high-grade complicated watchmaking, but with the development of the motor industry additional scope was found in the manufacture of speedometers. Magnetos have now been added to the output of the well-equipped works at Watford. The business will continue to have the experienced and practical guidance of Mr. R. R. North, the governing director.

Palmer Tyres.

The Palmer Tyre, Ltd., inform us that so far Government requirements still prevent them from executing orders for 750 mm. × 75 mm. Palmer Cord heavy motor cycle tyres, in the three-ribbed pattern, to fit 650 mm. × 65 mm. rims, and also for 26in. × 3in. Palmer Cord heavy motor cycle tyres of the three-ribbed and steel-studded pattern for 2½in. rims. They have, however, a good supply of 700 mm. × 80 mm. Palmer Cord heavy motor cycle tyres, ribbed pattern, to fit 650 mm. × 65 mm. rims, which motor cyclists will find quite satisfactory on most heavy sidecar combinations. They can still supply a 28in. × 3in. pattern tyre to fit American machines

Vaporine Petrol Substitute.

We are informed that all enquiries for the petrol substitute sold under the name of Vaporine should be addressed to Mr. A. Brierley, 22, Sir Thomas Street, Liverpool. There appears to have been some miscomprehension, leading to wrongly directed enquiries, as regards the vendors of this fuel.

A Change of Address.

As the Government is requiring such a large number of Simms magnetos, the manufacturers of these instruments, Messrs. Simms Motor Units, Ltd., have moved their headquarters into larger and more extensive premises at Percy Buildings, Gresse Street, Rathbone Place, London, W.

Morgans Obtainable.

Provided a prospective buyer can obtain a permit from the Ministry of Munitions to purchase a new motor vehicle, the Morgan Motor Co., Ltd., of Malvern, are in the happy position of being able to execute such orders immediately, as we understand that the company has in stock at least 200 complete sets of parts of standard models.

Facts about Welding.

We have received a brochure from Barimar, Ltd., 10, Poland Street, Oxford Street, London, W., entitled "Straight Facts about Welding," written by Mr. C. W. Brett, the managing director of this firm. The brochure shows how apparently hopeless fractures of almost every kind of metal have been made good by acetylene welding. Copies of the booklet will be sent free on application.

C.A.V. Magnetos.

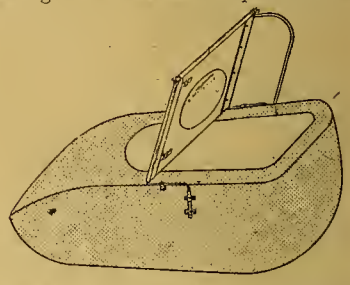
The manufacturers of the C.A.V. magnetos, Messrs. C. A. Vandervell and Co., Acton Vale, London, like many other firms, are not compiling a large catalogue at present, but are sending out instead brochures giving in concise form a description of the Type "3U1" for single-cylinder engines up to 4½ h.p., and Type "3U2" for engines up to 4½ h.p. firing at 180°. Another booklet enumerates the spares of these two magnetos, giving reference number and price, and is a useful list to keep at hand.

Review.

"The P. and M. in the Making" is an attractive booklet published by Messrs. Phelon and Moore, Ltd., Cleckheaton, Yorkshire, describing the manufacture of the famous P. and M. from A to Z. The book begins with an introduction stating that it is not practicable to produce a catalogue during the continuance of the war. It then goes on to show the various processes employed in the construction of the machine, beginning with the cylinder, then taking the reader gradually through the manufacture of the whole motor bicycle. The processes are briefly explained and clearly illustrated by high-class blocks. An interesting fact dealt with is the testing of the cylinder, which is subjected to a pressure of 400 lb. per square inch. After he has perused the booklet, the reader will cease to wonder why the Royal Flying Corps has adopted the P. and M. exclusively.

A Sidecar Screen.

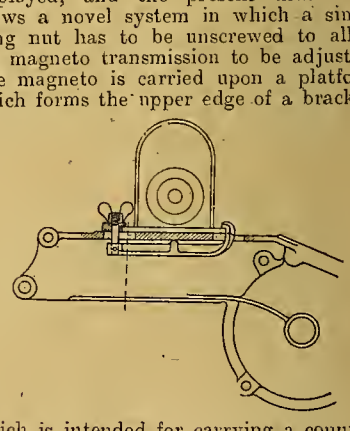
By this invention there is provided a simple form of windscreen which can be adapted to various sidecars, and which will occupy little room when not in use. The screen frame comprises an upright at each side connected by a cross-bar. The screen itself may be made of flexible waterproof material, such as hood cloth, into which is let a window of celluloid. One edge of the screen is provided with



spring buttons and eyelets, whilst the other has attached to it straps and buckles. Thus one edge is attached by means of the quick-spring fastenings, whilst the buckles afford an adjustment at the other edge, so that the screen may be drawn taut when in position.—W. E Boyce, No. 102,848.

Magneto Adjustment.

On motor cycles the magneto is usually held in position by four studs, so that adjustment or removal is not an easy matter. There are, however, one or two instances of alternative fastenings being employed, and the present illustration shows a novel system in which a single wing nut has to be unscrewed to allow the magneto transmission to be adjusted. The magneto is carried upon a platform which forms the upper edge of a bracket,



which is intended for carrying a countershaft gear box. Beneath the platform is arranged a lever, which is provided at its centre with a fulcrum block, and at one end with a claw. This claw passes up through the platform and engages a plate which carries the magneto. From the other end of the lever projects a stud, on which the securing wing nut is screwed.—C. G. B. Sangster, No. 102,913.

BOWDEN WIRE LTD LONDON

ESTABLISHED 1897

BOWDEN Wire, Limited, being wholly engaged upon production for the British and Allied Governments, are unable to execute any orders for private purposes until further notice They have in stock certain goods suitable for replacements. Customers are invited to state their requirements in this respect, and, if possible, these will be met

SIMMS MOTOR UNITS, LTD.,
FERCY BUILDINGS, GRESSE STREET, RATHBONE PLACE, LONDON, W.
And Dealers everywhere.

I SUBMIT there

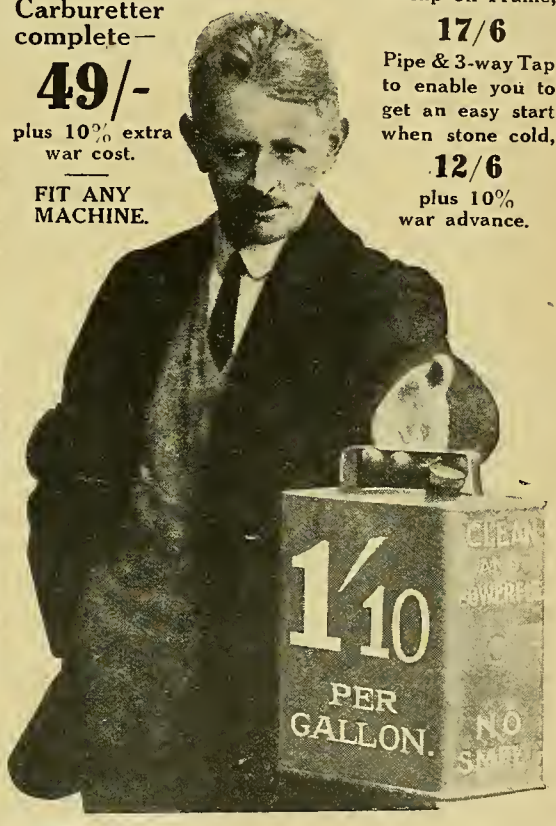
is a solid reason why you should adopt a BINKS CARBURETTER, viz.: YOU CUT YOUR FUEL BILL IN TWO

if you adopt my system and use my fuel. You can, of course, use petrol or benzol without alteration.

Price of Carburetter complete—
49/-
plus 10% extra war cost.

FIT ANY MACHINE.

Small extra Tank to clip on Frame,
17/6
Pipe & 3-way Tap to enable you to get an easy start when stone cold,
12/6
plus 10% war advance.



READ!

MY 3-PHASE JET DAMPING CARBURETTERS have such perfect vaporising properties that they enable you to use fuel at **1/10** per gallon in 42-gallon casks, which you are allowed to keep on your premises. Casks **12/6** each, returnable at **10/-** each. Your engine will tick over dead slow, and pull dead slow in traffic, yet give the full power. It is almost impossible to tell you are not running on petrol at **3/-** a gallon. It cannot damage your engine or soot it up, and makes Motor Cycling possible in these times.

I give you my personal assurance of the truth of what is stated above. Please send at once for full particulars of the carburetter, and also for my Treatise on Carburation, and terms of One Month's Approval Trial.

Owners in London invited to apply to Messrs. Oylers, Ltd., of 35, New Cavendish Street, who have facilities for supplying and fitting these carburetters.

C. BINKS, Ltd., Eccles.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., & Co., and crossed

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

TWO DRAWBACKS

exist at the present time for would-be Motor Cyclists. We have devised

TWO SCHEMES

to help our customers under the existing difficulties. Some people fear to take up Motor Cycling at the present time for two reasons.

First, the petrol question. They think that if they purchase a machine, they will not be able to run it for want of petrol. To alleviate this, we have decided to continue our policy, introduced during the petrol shortage of last year, of giving

PETROL FREE

in quantities up to 10 gallons to all who purchase a machine from us. As all our machines are tuned to run on substitute to the best of their ability, this should suffice, judiciously used, for a season's mileage.

Secondly, people fear that they may be called up, or become engaged on Munition Work, or under the National Service Scheme, and that they would then be encumbered with a useless machine. To deal with this, we are introducing our

REPURCHASE SCHEME,

which is equivalent to

HIRE AT 13/4 TO 30/- PER WEEK,

according to whether the machine is kept 1 or 6 months.

Briefly, our scheme is this:

We will sell any machine on our lists under the following written agreement:

If the machine is returned within a month from purchase, we will take it back, and refund the full amount paid, less the sum of £6 for the Hire, which works out at 30/- per week.

In two months, we will take back at £9 reduction, which works out at £1 2s. 6d. per week.

In three months, at £11 reduction, or 18/- per week.

In four months, at £13 reduction, or 16/- per week.

In five months, at £15 reduction, or 15/- per week.

In six months, at £16 reduction, or 13/4 per week.

Thus, our Customers need never fear that they will not be able to dispose of their machines at once, if called up, or if other necessity arises calling for an immediate sale.

The same rates apply, whether the machine is worth £30 or £130. The Scheme only applies to cash deals.

We are not prepared to hire machines at any terms, except under the above scheme.

Of course, if our customer can get a better price elsewhere, when he comes to sell, he is under no obligation to return the machine to us; but, if he does not do so within six months, we reserve our right not to repurchase.

Our usual guarantee applies to machines sold under this scheme.

We ask our clients to co-operate with us in making this scheme a success; and we venture to think that many will take advantage of it, when they realise that they obtain a guaranteed machine, a Free supply of Petrol, and a definite promise of repurchase at a definite fixed price.

THERE CAN BE NO EXCUSE FOR ANYONE HESITATING NOW.

We have **100 Machines** in Stock at the time, including:

Alldays Matchless, Alldays Allon, Ariel, Brown, Blackburn, Clyno, Douglas, Enfields, Excelsior, Edmund-J.A.P., F.N., Grandex-Precision, Grandex-Villiers, Harley-Davidsons, Henderson, Humber, Indians, Ivy, Kerry-Abingdon, Martin-J.A.P., New Imperial, N.S.U., Omega, Puch, Quadrant, Premier, Rover, Rudges, Royal Ruby, Singer, Scott's, Triumphs, Torpedo-Precision, Wanderer, Williamson, Zeniths, etc.

Also **Carden, Morgan, Grand Prix, Briton Car, Bayard 8 h.p., Trumbull, Morris-Oxford,** etc.

NEW Hudson Combination, 3½h.p., lamps, horn, tools, etc., new tyre on rear; £31.—Walsall Garage, Walsall. [X6607

3½h.p. New Hudson Combination, coachbuilt, 3 speeds, excellent condition; £11/10 cash, and 12 monthly payments 56/-.—Parkers, St. Giles', Oxford. [X6633

NEW Hudson, 4h.p., with folding Paragon sidecar, goes through 30in. door, saving garage, speedometer, etc.—1, Duke St., Manchester Sq., W. [8544

NEW Hudson, 1915, 3-speed countershaft, War Office model, all accessories, splendid outfit; £48; extended payments arranged.—Service Co., 292, High Holborn, London. [X6727

NEW Hudson 3½h.p. Combination, late 1913, 3 speeds, and clutch, speedometer, lamps, 2 generators, good condition, and spares, etc.; bargain, £25.—E. Wright, School Hill, Chapel End, near Atherstone. [X6712

1913 3½h.p. New Hudson, with cane sidecar, 3-speed, kick start, all lamps, etc., enamelling and plating guaranteed absolutely perfect; £30; extended payments arranged.—Jones, Garage, Broadway, Muswell Hill. [8769

1915 4h.p. New Hudson Combination, countershaft 3-speed, clutch, kick start, Lucas accessories, luxurious sidecar, outfit in new condition, run under 2,000; sacrifice £45.—Box L3,195, c/o *The Motor Cycle*. [8784

NEW Hudson 1913-14 Combination, 4h.p., 3-speed gear, free engine, clutch, new tyres, belt, Miller lamp set, all accessories, splendid condition; trial; owner enlisted; bargain, £27/10.—174, Barcombe Av., Streatham Hill, S.W. [8546

New Imperial.

J. A. STACEY, 12, Ecclesall Rd., Sheffield, for 1917 Imperial-Japs. Immediate delivery. [7862

COLMORE Depots, Manchester and Leicester, for immediate delivery of New Imperial motor cycles. [0805

1916 New Imperial, 2-speed, almost new, in splendid order; £28/10.—Jones, Garage, Broadway, Muswell Hill. [8503

NEW Imperial-Jap, 2½h.p., 1915, 2-speed gear, T.T. handle-bars; £24/10.—Eagles and Co., High St., Acton, London. [X6742

1915 New Imperial-Jap, 2½h.p., 2 speeds, lamps, horn, spares, little used; 23 gns.—Pelly, Kington, Herefordshire. [X6766

NEW Imperial-Jap; immediate delivery all models.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter, and Tavistock Rd., Plymouth. [0839

1916 New Imperial-Jap, 2-speed, 2½h.p., new in May, in perfect running order, P. and H. head lamp; only wants seeing; £34.—F. Caudrey, Chartridge, Chesham, Bucks. (D) [X6665

NEW Imperial 1917 Models for immediate delivery; model 1, 39 gns., No. 2 46 gns.; several second-hand 1916 machines from £30.—Colmore Depots, 211, Deansgate, Manchester, and 31, Renshaw St., Liverpool. [0886

NEW Imperial 1917 Models in stock; light tourist, 2 speeds, countershaft, 38 gns.; clutch and kick starter models, also ladies' models ready to drive away.—P. J. Evans, Controlling District Agent, John Bright St., Birmingham. [8698

Norton.

NORTON 1917 Big Four Combination; £89/10, first cheque secures.—Percy and Co., 337, Euston Rd., London. [8800

O.K.

O.K. Junior, 2¼h.p., new May, 1916, very little used, equal to new; £25.—Box 747, c/o *The Motor Cycle*. [X6806

O.K., 1914, 2¼h.p., 2 speeds, T.T. bars, splendid condition; 14 gns.; Forces.—Davies, Cranham's Cottage, Cirencester, Glos. [8630

P. and M.

1913 P. and M., 2-speed, condition good; a bargain, £26.—Ross, 86, High Rd., Lee. [8654

1912 P. and M. Coach Combination, 2-speed, speedometer, P. and H. lamps, new condition; £33.—47, Honeybrook Rd., Balham. [8760

THE MOTOR CYCLE
ESTABLISHED IN 1903
AND FOR OVER SIX YEARS THE ONLY PAPER SOLELY DEVOTED TO THE PASTIME

The Flywheel Magneto.

THE British magneto industry has already expanded to such an extent that it is a foregone conclusion that after the war the whole of the requirements of motor manufacturers will be satisfied by home products. Thus for the first time the motor industry of this country will be self-supporting—a condition of affairs we have for years striven to attain. With the characteristic tardiness of Britishers to rally themselves, the support of our agitation was at first by no means whole-hearted, and the position for a long time remained indefinite. Now, however, numerous works are established and the weekly output of magnetos is at the present moment very considerable—sufficient to satisfy all peace-time demands. It was, in fact, stated officially the other day that 165,000 magnetos had been produced in British factories since the commencement of the war. At the present moment the factories are, of course, engaged upon Government work, and, in passing, one wonders what we could have done in the matter of magnetos for internal combustion engines had the erection and equipment of works been delayed when war broke out. Now the magneto which is being produced for motor cycles largely follows standard pattern, and some makers have come to regard that instrument as finality. It would be a pity for all to assume that improvements are not possible, for interesting developments are quite conceivable. Indeed, we have long since regarded the type of magneto fitted to the two-stroke motor cycle as not thoroughly in keeping with the simplicity of this type of mount. Already we have a motor cycle entirely devoid of any gearing between the engine and magneto, and instead a neat little magneto machine incorporated within the outside flywheel. By this arrangement not only is the manufacturing cost of the magneto itself considerably reduced, but the need for driving gear is completely avoided. We notice other patents recently published bearing upon this same development, and it is not unlikely that the flywheel magneto may ere long attain prominence in the motor cycle world, particularly in the lightweight field. It is well therefore to throw out a timely hint to magneto manufacturers that it may not be sufficient to produce a magneto machine on orthodox lines. The design of magnetos will progress just as the design of motor cycles and their other appurtenances progress, and it behoves the designers employed by firms engaged in this electrical branch of the industry to be alive to the point.

Concessions to Service Men.

TWO minor items dealt with in this issue which affect numerous readers are (1) the question of keeping in condition the motor cycles of friends at present in the Services, and (2) the necessity of such Service men taking out (1) a local taxation licence and (2) a driving licence for a single run which they may enjoy during a brief leave.

The first question is one quite easy of settlement. The other, we are afraid, entails a long and strong pull to obtain a Government concession. We use the term "concession" advisedly, though, as a matter of fact, in many cases the men in question took out a licence for twelve months and joined up long before the expiration of that time, so that in effect they have several months of ownership due to them. The same remarks apply to driving licences which every driver of a motor cycle or motor car must possess.

Our sole anxiety is for the interests of riders who are doing their part in the country's cause, and who, during a few precious days' leave, would enjoy nothing more than a spin on a motor cycle to bring back old memories and delights. It is not a complicated matter to adjust these minor points in a manner which would enable any member of His Majesty's Forces to enjoy a trip on the open road, and we hope something may be done.

An index to the advertisements in this issue will be found on the page facing the back cover.

DUG-OUT DEBATES

THE war and the new army with all its varied motor sections have undoubtedly caused numbers of men to become enthusiastic over, or interested in, motor cycles—men who previously took no interest whatever in such things. Judging by the number of queries, usually of the hackneyed type, that emanate from dug-outs "somewhere in France," or from other fronts, it is evident that motor cycle discussions are a pretty regular occurrence in "off" moments, even among men who are not in any way connected with the motor sections. Apparently the motor cycle and its problems make pleasant topics and discussions to pass the time during these long winter nights in the trenches. The queries we receive are remarkably diverse, but, curiously enough, the majority from the trenches revive very, very old controversies. Some have been answered and discussed time and again in these columns. We are going to forestall any more queries of the same kind, and have collected with that object a few of those which most regularly recur. Perhaps our comments will bring enlightenment to some of our comparatively new readers.

Which Wheel Lifts?

A rare old chestnut which crops up as regularly as clockwork—a very curious fact, considering the apparent obviousness of the answer. The form in which the question is most commonly put is, "Which direction does a sidecar outfit have to be turned in order to cause the wheel of the sidecar to lift?" The answer is, of course, a turn to the left, if the sidecar is fitted to the left side; or right, if the sidecar happens to be on the right-hand side. It is a law of nature that any body, if once set in motion, continues to travel in a straight line; therefore, if some force tends to alter the direction of travel, the natural tendency of the body is to resist that force, and thus the body tries to slide or skid—back to the original direction. In the case of a motor vehicle, however, the wheels grip the ground sufficiently to prevent the skidding tendency, but the fact that the vehicle tries to continue in a straight line causes the wheels on the inside of the curve to lift.

Why does an Engine Knock?

This query is rather more permissible, as apart from the knocking which sometimes occurs in absolutely new engines, and is in consequence somewhat difficult to account for, there are quite a number of somewhat obvious reasons which may explain this unpleasant but familiar sound. In some cases it is easy enough to explain the exact cause of the noise; but in others, although it is easy enough to say how the noise can be cured, it would be difficult, if not next to impossible, to state definitely and exactly what is taking place inside the engine. The following conditions will often account for knocking. The two commonest conditions which will cause any machine, irrespective of its general condition, to knock, are too much air and the ignition too far advanced. Other reasons are *worn bearings*, most commonly the big end of the connecting rod, though any of the other bearings being worn may cause knocking. *Excessive carbon deposit, unsuitable plug electrodes*, or *too high compression* will cause pre-ignition and overheating, with knocking as a consequence. Under-lubrication may also cause most serious knocking; while piston rings which are a loose fit in their grooves cause a very elusive tapping, similar to that of a worn tappet gear or loose bearing. The metallic knock which sometimes occurs in an absolutely new engine can be put down to many causes, but up to the present no one has really definitely proved what it is.

"The road conditions in France are truly terrible," says Pte. A. Greenhalgh, A.S.C., M.T., "but we carry on cheerfully. The marvel is the motor cycles standing the ordeal, but they do, for mine is running as well to-day as when I had it new." Greenhalgh is attached to the Anzacs as a despatch rider.

The Front Wheels of a Car.

Another old chestnut is the argument as to whether the front wheels of an ordinary motor car are pushed or trailed. "Of course they are pushed," ejaculates the normal person, but the wily one of the party prefers to think otherwise. He argues that the springs do the work, and since the forward end of the springs only are permanently connected to the frame, the axle and its wheels must be trailed. When the argument becomes fierce—they write to *The Motor Cycle* to settle it. Our ruling is that both parties are right: and in any case does it matter *very* much?

The Fastest Speed.

Another question which seems to be interesting men in the trenches is the speed attained by various motor cycles. Such queries as "What is the highest speed ever attained by a motor cycle?" or "What is the highest speed ever made by a motor cycle in England?" and again, "Who holds the 500 c.c. single-cylinder hour record?" occur almost daily.

The highest speed ever recorded is 103 m.p.h., which was attained by Jack Booth on the Gawler Road, in Australia, over a distance of one mile, on an eight-valve twin Indian.

The highest speed yet attained in England is 93.48 m.p.h., by S. George, also on an eight-valve Indian, at Brooklands, over a distance of one kilometre.

The 500 c.c. single-cylinder hour record was last made by G. E. Stanley on a 3½ h.p. Singer on October 15th, 1912, when he covered 67 miles 782 yards in the hour.

The Hour Record.

The hour motor cycle record is held by A. J. Moorhouse, who, riding a 7 h.p. twin Indian, covered 70 miles 1,388 yards in the hour at Brooklands on November 21st, 1911. Moorhouse, it will be remembered, was killed at Brooklands during a B.M.C.R.C. one hour race on April 20th, 1912. At the time of the accident he was riding inside his own record time.

Ford jokes also are evidently popular in the dug-outs, for we receive numbers of these, supposed to be new and original, which we heard years ago.

Nothing Loose in Twelve Months.

THERE are two spring-framed machines in my garage, one of which has done over twelve months of hard work, the other about nine months. On the first machine not a single part has ever shaken loose in about 9,000 miles of rather fast work; no nut or screw has ever been found in need of tightening. On the second machine two or three details have worked loose at various times, but they have all been parts which depended on the front fork for insulation from road shocks, namely, the hooter, the front mudguard, and so forth; though machine No. 2 is inferior to No. 1 on this score, it is nevertheless infinitely superior to the average rigid-framed machine. In neither case have I on any single occasion overhauled the nuts as a precaution; they have simply kept tight throughout the whole season without any attention whatsoever; and I am sure no rider of a rigid rear frame can claim to have done a season's hard work without finding a nut slack. This implies that the advice given in motor cycling handbooks—to go carefully over all the nuts once a week or so—is becoming obsolete, and that the twiddly bits of motor cycles should shortly become as vibration-proof as those on a good car.

A Sturdy Midget.

A COUNTRY agent asks what has happened to the $2\frac{3}{4}$ h.p. overhead valve J.A.P. engine which used to do its 60 m.p.h. ten years ago in the hands of men like the Colliers and Harry Martin? He points out that the modern baby engine cannot approach this performance, and wonders why similar engines are no longer exploited. I suppose the simple fact is that ten years ago some judges fancied that the 350 c.c. engine would satisfy the demand for solo work, and so manufacturers spent money on exploiting such types. It gradually became clear that the sidecar and fast hill work interests wanted a little more power, and so the trade turned its attention to larger sizes. The market for "baby" engines to-day is a market which is not interested in speed. The Douglas is almost the only 350 c.c. engine which has been habitually exploited on the track, and it stood for some years in a separate class, as it was produced as a direct rival to the $3\frac{1}{2}$ h.p. on its own ground, even though sidecar interests have since compelled its makers to offer a 4 h.p. Nobody dare prophesy what the next Junior T.T. will bring forth; in the past this event has been something of a feeler, both technically and commercially. The public have not decided what kind of lightweight they really want; the trade have not discovered an ideal specification, and engineers are still coquetting with the two-stroke, the small flat twin, the medium flat twin, the small single cylinder, and the miniature V twin. If I had to hazard a guess, it would be that the near future of the lightweight rests with the two-stroke and the flat twin.

Smashed Gears.

I AM a little disquieted by the numerous cases of smashed motor cycle gear boxes which have come to my knowledge during the past year or so. Wherever I have been able to investigate the facts of a particular case, the makers have proved to be blameless; and the damage has invariably been due to some stupid piece of mishandling by a clumsy driver. The cause does not affect the fact that frequent gear box troubles are very bad for the sport. It is often impossible to convince the user that he can blame nobody but himself, and his grumbles will not serve to popularise the machine he rides, whilst his troubles will be common knowledge in his district, and will create a public impression that motor cycles are expensive and unreliable, whereas the simple truth is that the modern gear box is very far from being foolproof. One is almost inclined to suggest that the plan of interconnecting the clutch and the gear lever, as adopted by a few American makers, may be worth consideration. At any rate, the bulk of these injuries are due either to the driver altogether omitting to declutch for a gear change, or to his failing to synchronise his clutch and gear work. Cases of this very elementary blunder have put crack riders out of the T.T. before now—they have confessed as much to me in confidence; and, if experts can be guilty of such aberrations in moments of excitement, it is obvious that a nervous and excited novice is hardly to be trusted with a light and fragile gear box. In some cases imperfect design of the gear control may be partially answerable. On a good car the gear lever can be trusted to slide smoothly into any of its five or six positions under finger pressure. On a motor cycle the driver has to steer and balance with one hand whilst he is changing gear, and his left hand is very possibly doubly employed with a clutch lever as well—if not, his foot is busy with a pedal. The chances of a blunder are considerably enhanced if the "gate" is very narrow and full of corners, or if the springiness of the control necessitates some force to coax the lever into the highest and lowest notches, or, again, if the design makes it easy for the lever to slip past the intended notch. Whatever solution is adopted, all these details require the closest attention from some of our manufacturers, especially as novices take out these machines—which are more difficult to drive than a car—after very superficial instruction indeed, and with no mentor aboard to supervise and criticise their early efforts. More attention should be paid to driving lessons, now that our machines are more complex and more liable to injury when mishandled.

More Sporting Reminiscences

By Veteran

FIFTH INSTALMENT. (Previous Articles appeared in our issues of April 13th, June 15th, Sept. 14th, and Dec. 21st, 1916.)

I ALWAYS fancied that reminiscences ceased to charm till one reached the Darby and Joan era, and spent one's evenings by the fireside with a gouty leg cocked on a hassock, and a basin of gruel somewhere adjacent; but the Editor says my memories of bygone days go down well with the temporarily off-saddled boys in France, and he commands me to ransack my brain pigeon-holes for another instalment. Like the famous French preacher, I can preach to any text to order, provided it be motor cycling and not Scripture; what will ye have, gentry? Tyres? Troubles? Or assorted? This week I think it had better be a random lot.

A Trial of Six Days' Duration.

There is a vein of altruism in my nature, which has more than once betrayed me into helping lame dogs over stiles. It may be sound enough in financial matters, when a coin or a cheque ends the business, but it is the deuce and all when it sets you to assist a struggling friend in the motor industry by buying and riding the bad machines which he is trying in vain to sell. My first real piece of unselfishness occurred in connection with an impecunious friend, who thought he had invented a brilliant motor bicycle, but who lacked the money to push it. I intended to spend part of my annual holiday on a six days trial, and, half believing in his boasts about his new engine, I bought a sample and entered it. The machine was reckoned as 2¾ h.p. in those days, and possibly developed that figure on the bench when new. It ran beautifully the first day from a mechanical standpoint, and I looked forward to a very pleasant week. The one fly in the ointment assumed the form of tyre troubles. The covers were apparently tissue paper; they punctured whenever we passed an ironmonger's, and burst if they smelt a broken bottle in the hedge. I took maximum time over most controls, and finished the day's run about 10 p.m. Tyre troubles could be repaired overnight under the rules then in force, and I sat up into the small hours fitting two new covers by candle-light in an odorous stable; I should have got to bed earlier if the official observer had not been a merry soul. As it was, he refused to superintend my labours until the last of the boys had gone to bed.

More Tyre Troubles.

So it was nearly breakfast time before I got to roost, and the shaving water arrived in the middle of my first beauty sleep. The new tyres were the same brand as the others, and bursts and punctures occurred next morning as regularly as the tack-tack of a machine gun on a sweeping traverse. Moreover, my untrustworthy friend was evidently a rotten metallurgist, for it became clear in the course of the second day that the piston rings had worn down flush with the piston, and eke that the exhaust valve was scaling off its face in great chunks. At first I supposed that the valve was the sole culprit, and though it had a 40 lb. spring and the kit contained no remover tool, I fitted a spare, only to discover that the missing compression would not return, and that the rings were the real offenders. By midday there was about as much compression left as a feather can produce in a briar pipe. I was doing l.p.a. on every grade exceeding 1 in 80, and there was plenty of 1 in 8 ahead along the road. Being a man of brawn in those days I kept going until the Friday, putting on at least one new cover daily, and excoriating my knuckles swopping exhaust valves with a screw-driver as my main tool. On Friday evening the

More Sporting Reminiscences.—

machine began to go crabwise on a bone dry road, and I discovered that the front down tube of the frame was only attached to the steering head by a precarious flake of varnish. I trained home in a pet, and slept for a week.

By next summer my friend claimed that his engine was perfect, and I bought another sample for that year's six days, only stipulating that he should fit a two-speed gear, as my calves ached at past memories. Not having had time to design a gear of his own, he fitted a proprietary chain-driven gear.

I picked up the machine at Penzance, and liked the look of it; very few entrants had variable gears, and I promised myself some scores off ancient foes.

How I Won a Gold Medal.

The first day's run to Taunton was something of a terror at that era, and my machine wouldn't do more than 24 m.p.h. all out. I hadn't a notion what was the matter with it, and the single-geared men nearly fell off their saddles with glee as they saw me toiling up the long Cornish and Devon rises at about 6 m.p.h. on bottom gear. This humiliating weakness continued all Monday and part of Tuesday; but I kept going in the Micawberlike notion that something might turn up, or a brain wave occur, and schedules then allowed us 16 m.p.h. maximum time. By dint of taking all downhill bits on full throttle I kept inside this figure. When we reached Gloucester on the Tuesday I decided that bad oil must be my trouble. I drained my tank, put in two new valves, and filled up with genuine sealed Price's. Hey presto! I could do 45 m.p.h. anywhere. I kept busy wiping the eye of my single-geared pals till we got well up in the Highlands, where we struck a Scottish mist, and real slime. The chain drive had buckled my light frame, and the side-slips were marvellous to behold. It wasn't a question of slide, tug, wobble, and recover. It was just wop—and heavy sideways impact with the 'ard, 'igh road—like being charged by a 14-stone soccer back when one is on one leg. Entering Inverness I almost sat down and cried. Better men than I on true frames were tumbling off in every direction, and my machine simply would not stand up. I had a rare punishment. Further north things improved, and thanks to my gear I made one of the very few clean ascents of Berriedale, amid much cheering. After that the chain drive bent my crank pin; my valve lifter broke; and various other misfortunes overtook me. However, I struggled into John-o'-Groat's in this wise. My overalls were torn to ribbons. My lamp bracket had gone phut in a side-slip, but as almost the only "condition" rule compelled us to finish "with lamps," my lamp hung round my neck with picture cord. My gearshaff had developed a habit of jumping out of mesh, so my right hand carried a huge spanner with which I clumped the shaft whenever it jerked free. Between my teeth was a penny attached to the handle-bars with string for holding the valve open to get starts with. My crank pin being bent, the engine was developing about one sardine power, and I was driving noisily on the low gear in clouds of smoke. But I was up to time, and got my duly advertised gold medal sure enough! The machine could never have got back to Wick, and I left it to be carted to railhead by a Groat's gillie.

Another Lucky "Gold."

An even more remarkable "gold medal" was won in that same trial by a whilom famous passenger machine, which spun back to Wick just ahead of the car which carried me. About halfway back, say ten miles from the finish, we saw the tops of its rear tyres gracefully incline inwards, as its back axle collapsed. Needless to say, this interesting detail did not appear in the subsequent advertisements.

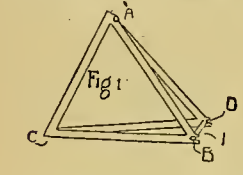
Adventures in a Tricar.

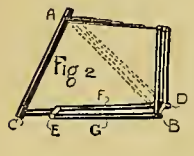
Not long after came the epoch of projectile tricars, and, needless to say, I soon found myself afflicted with one of the worst. It was a beauty to look at. I then resided in a London suburb, and I can still remember the crowd that assembled when we uncrated it—shining nickel, red leather, Napier green panels, with white and black stripes. In motion it was less admirable; for example, nothing would induce it to cross greasy tramlines on the straight. On its maiden run it had five or six essays to cross a tramline junction somewhere near Brixton, and shied right round every time. Finally, I learnt that the dodge was to go very fast, and aim its nose at three o'clock; it would skid round to nine o'clock, and the pace would swish it across in mid-skid. To see what the machine would do, I decided to start from London for Coventry at 4 a.m. on a summer day, and put up a phenomenal average speed, of which its 15 h.p. engine was undoubtedly capable. My driving of that projectile through the northern suburbs what time milkmen and Covent Garden vans are astir was lurid to a degree, and by the time we got clear of town there were no surviving brakes. Then it began to rain. I was doing a cool fifty up a gentle curved slope somewhere in the Bletchley district when an enormous skid occurred, and I found myself tearing along on the top of a turf bank some three feet above the road. I had barely realised this before the machine rammed its nose deep into a heap of manure; the wheel took me in the tenderest portion of the anatomy with a hideous "wop," and I remembered no more. When I came to I staggered towards a solitary house, and was immediately assaulted by whole battalions of dogs; however, the keeper of the dogs' home was a good Samaritan, and before very long a car came out from Towcester to tow me in. The tower forgot I had no brakes, and downhill I invariably began to ram him. At the last moment he would hear my shrieks and accelerate; having no non-skids he would then begin to side-slip. Side-slips are always thrilling, but for real fear put me in a towed car attached by a 10ft. rope to a big car which is out of control. We got the projectile repaired, and late that night I restarted for Coventry. The manure heap had binged my silencer off, and near Daventry I had to stop the engine, as some racehorses objected to it in the dark. My lamps gave out before I discovered anything amiss, and then it would not start; with my last match I discovered that a nut had dropped off the air control, and that the satisfactory resistance of a lever on the quadrant did not prove there was anything doing at the carburetter end. I slept at Daventry, and next day my accumulator ran down four miles out of Coventry. I staggered into the works more dead than alive, having taken exactly thirty-six hours on the projected record of ninety-seven miles.

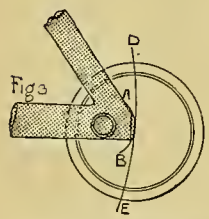
Rear Springing of Motor Cycles

A Doubly Eccentric Hub which Preserves the Correct Distance between the Driving Centres.

OF the many problems which motor cycle manufacturers must tackle in earnest after the war the subject of rear springing stands out prominently, for one thing is certain, viz., that the trend of motor cycling is towards increased comfort, and the rigid back frame will soon become as rare as rigid front forks are at present. A great number of designs have been evolved, many good as far as solo work is concerned, but in other cases there is a tendency towards the same weakness, *i.e.*, lateral stiffness.







(1) A triangulated rear frame. (2) Spring frame of common design lacking in lateral rigidity. (3) Eccentric hub.

The common difficulty lies in producing a form of design which combines the merits of the rigid frame and still allows a vertical action of the wheels, which I would suggest can be done in a perfectly valid and mechanical way.

The vital point is the amount of up and down movement you must give to the wheels in order that road shocks be eliminated, and this is where most designers differ. For my part I think a 2in. movement is sufficient, and I base my opinion on the following facts. The amount of movement or yield between an iron-tyred lorry and one shod with solid rubbers can be measured in eighths of an inch, yet the gain in comfort is enormous, while the difference in yield between a well-inflated pneumatic and a solid rubber tyre does not exceed one and a half inches, if as much, so it will be seen that, taking everything into consideration, two inches of vertical movement will give almost complete freedom from road shocks.

The Sidecar Question.

Having settled this point, the next is to consider whether your spring frame is to be strong enough to take a sidecar, and to this question the great majority of riders must say "yes." After all, solo riding is only for the few; the greatest number want a machine which can take a sidecar. Now the strains and stresses set up in a sidecar machine are much greater and more complex than the strains in a solo machine, and a spring rear frame which might do very well in a solo would soon wear itself to pieces in a combination. Therefore, if rear springing is to become universal, it will have to be at least as strong laterally as the back triangles of a rigid frame.

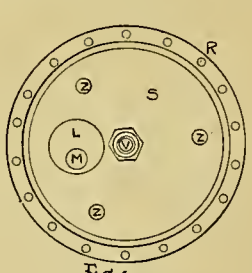
Twisted Frames.

Fig. 1 shows the system of triangles on which the rear frame is constructed, and fig. 2 shows what is practically the only type of spring frame at present on the market, and how the strength of triangle ABD is altogether lost, while that of DCB is weakened by the hinge E. Now it is the triangle ABD which gives the rear portion of the cycle frame its lateral rigidity and strength, and when it is taken away the whole remaining structure becomes unstable. To counteract this to some extent the legs F and G are made of heavier tubing, but this does not help much. Sooner or later these legs will get a twist or "set," and then the drive is out of truth. The twist comes from many sources—a sudden swerve, the wheel striking a deep rut or kerb will do it, whereas a rigid frame would be strong enough to overcome the sudden strain. By lengthening the hinge E and the axle I greater strength is obtained, but at the best the ability of legs F and G to stand twisting strains is not great, and I doubt whether this type of rear springing will long survive.

Some designers leave the triangle ABD intact, but miss out the through axle I, which is really the keystone to the whole structure.

The Eccentric Hub.

Now it will be seen that the problem is to keep the four triangles ABD, ACB, ACD, and DCB intact, and still give the wheel a vertical movement. This can be done in only one way, that is by mounting the hub eccentrically to the axle, as shown in fig. 3, but it has the great disadvantage of constantly altering the tension of the drive, which makes its use impossible. The hub rotates through arc AB, while the radius of the drive is represented by arc DE.



Plan and sectional views of the doubly eccentric hub.

Rear Springing of Motor Cycles.—

At the same time, I have always regarded the eccentric hub as offering the best solution to the problem, and after experimenting with it for some time I designed a hub which has its advantages and without

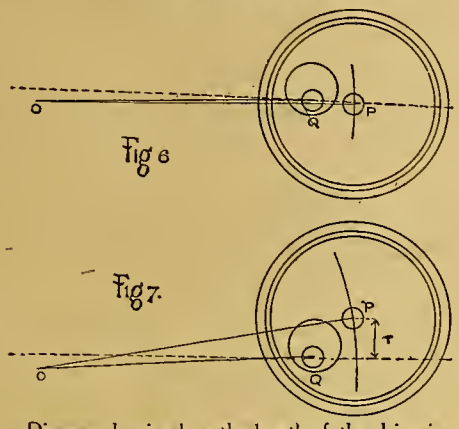


Diagram showing how the length of the drive is unaffected by the rise and fall of the axle in the doubly eccentric hub.

its disadvantage, for it can rotate through practically any radius, under control of a distance or radius rod. This hub is shown in figs. 4 and 5, and its chief feature is that, instead of the axle M passing directly through the side plates S, as it does in fig. 3, it passes through a floating eccentric L. This eccentric L allows the whole hub to rock slightly forwards and backwards on its axle M. This is shown in figs. 6 and 7. The distance OP represents the radius rod, while OQ is the length of the back horizontal stay or fork into which the axle M is secured. It will be noticed that the hub has moved vertically the distance of T, yet the distance between O and P has not varied in the slightest, so that the tension of the drive, be it chain or belt, remains unaltered. The hub consists of five elements, the shell R, the side plates S and U, with their ball bearings, the floating eccentric L and the centre piece V; steadying pins Z can be added if necessary.

Two great advantages are obtained by this design in preference to hinging the frame; first all the advantages of the rigid frame are retained, and secondly the same type of hubs can be utilised in springing the front forks and also for the sidecar wheel. Thus they are all interchangeable, and having the same amount of movement the motion of the whole combination is in harmony.

The Complete Machine.

Fig. 8 gives a good idea how a motor cycle with front and rear springing on the lines suggested looks. The back carrier is utilised to connect the leaf springs to the eccentric hub, while the front springing is somewhat after the "Osborne" and "Indian" designs. Although both the wheels have two inches of vertical movement, the whole frame is as stiff laterally as though they were built into a rigid frame. The need for front hinged forks is also removed, which makes for strength. The radius rods keep the hub always equidistant from the gear box, and they are continued upwards until they meet the legs of the carrier.

The hub is simple to make, and the time taken to remove the front or back wheel from the frame need be little more than the time taken to remove either from a T.T. machine. With an all-enclosed

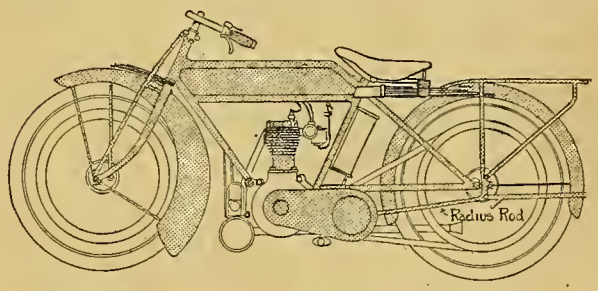

Fig. 8.—General view of machine fitted front and rear with doubly eccentric hubs.

chain drive it would be a bit more complicated, but so would any spring frame of the hinged type, and it has this point in its favour: it does not require the chain case to move with the wheel, so rattling of the case or the chains would become a thing of the past.

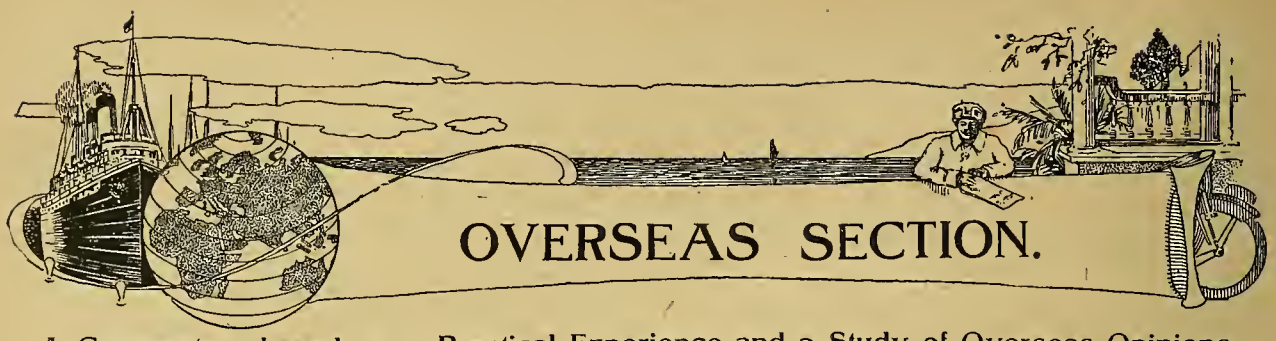
JAMES MARTIN.

NEW REGISTRATION ACT.

Some Advantages as Applied to the Motor Cycle Trade.

THE Registration of Business Names Act was passed the latter part of December. It is an Act which affects every trade in the kingdom, and none more than the motor cycling industry. It is a surprising fact how little interest the passing of this measure has caused, and yet no statute with such far-reaching results has been passed for many years. The two main objects of the Act are: (1) To prevent fraudulent trading. (2) To eliminate enemy control of business establishments. To secure these objects it has been made compulsory for a trader, who trades in a name not his own, to register the trading style and the name of the proprietor with the registrar of the district in which he trades. In the case of a partnership firm so trading, then all the names of the partners must be registered. The registers will be open to the public for inspection, and, not only so, it will be necessary for the notepaper, etc., used in the business to contain the true names of the partners.

This Act will come as a real boon to motor cyclists. After March next a motor cyclist, whether he is buying a machine or merely calling at a wayside garage for a tin of petrol, will know exactly with whom he is dealing. It will be no longer possible for a man to hide his identity under the old style of "Garage." It is an enactment which will help very considerably to breed confidence between the trade and the public, and this particularly applies to the second-hand market, where confidence unfortunately has on many occasions been severely shaken through certain dishonest practices which have been encouraged by the system of trading which will soon have to cease.



OVERSEAS SECTION.

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

SINCE the publication of our last Overseas issue we have experienced in the British Isles a spell of weather almost Arctic in its severity—a period a unrelenting snow and frost, which has helped the practical rider to realise what our readers in certain parts of the world have to contend with during the winter months. Throughout this spell we used our machines continuously, though chiefly for short business trips, and for running to and from the office, and the exceptional weather conditions brought home one or two points which were not, perhaps, very fully realised hitherto.

The first of these was the exceedingly heavy nature of war time petrol. Even the baby two-stroke refused to push off on the glassy surface after a night amidst the icicles till the old familiar remedy of a kettle of boiling water, poured over the induction pipe, had been resorted to, a dodge which saved endless breath and exertion. We found also that carbide generators were not much good unless placed in such a position as to obtain the benefit of the heat from the cylinders—and even then it was, of course, necessary to thaw out before starting. On the whole, we envied a companion with an electric installation, the armoured accumulator stowed away in a sheltered nook of the frame proving thoroughly adequate for the light solo mount this man rode.

LUBRICATION AND ITS ADMINISTRATION.

COMPARED with the perplexing matter of lubrication, these, however, were minor points. One of the machines we rode during the cold snap was a small two-stroke, dependent upon sump feed and a mechanical arrangement whereby crank case suction brings the oil through. Hitherto we have regarded the oiling system of this little machine as all that could be desired, but with the coming of the relentless frost the fun started. We found that on short journeys the engine got no oil at all unless the feed valve were opened fully, then, immediately the crank case became warmed up (which it did quickly owing to an efficient hot air intake), the engine would flood with oil ere one had time to wake up and reset the adjustment. If, therefore, the oiling was set for short journeys, it was quite wrong for journeys of any length, and *vice versâ*, with the result that the system, indisputably excellent for normal conditions, would have been much improved had it been possible to make the adjustments without dismounting, the present regulation being by a grimy screw situated amidst the most grimy portion of the whole engine.

WEAKNESSES OF A MECHANICAL SYSTEM SHOW UP.

THE other machine, a small twin, was fitted with a mechanical oil pump, having external connections and an oil tank some distance from the cylinders. The system hitherto has proved infinitely superior to anything in the way of hand pumps or automatic feeds, but during the cold snap those long thin external connections, conveying oil from a tank of almost solid lubricant and forcing it to flow along their almost microscopic bore exposed to a freezing draught, were a source of endless trouble. Indeed, the oil flowed when it took the mood and stopped unexpectedly, leaving one in a state of perspiring uncertainty as to the level of the supply inside the crank case.

Mechanical lubrication is undoubtedly desirable, but, as we have urged before in these columns, the pump connections should be enclosed in the crank case and as short as possible, otherwise the flow of oil is readily affected by the atmospheric temperature.

A SPRING FRAME "SUBSTITUTE."

THERE is a lot of talk of substitutes just now. How does the idea of spring suspended seat-pillars, dealt with in our issue of February 8th, appeal to Overseas riders as an intermediary in the direction of the spring frame? A possible half measure, perhaps; but most of us are not out for half-measures. Still, we must bear in mind that even in its ultimate and finally developed stage the spring frame will probably fall short of our ideals. It may effectively insulate the rider, it may even be designed to retain positively the vertical accuracy of the back wheel, but it will inevitably add complications, and increase the number of wearing parts.

The problem is indeed a knotty one. The amateur genius is constantly bringing before us the absolute simplicity of the matter; but the spring frame, ere it can be adopted with any degree of success, must possess many properties which do not immediately meet the eye. The road to its final establishment can only be paved over the remains of thousands of scrapped models, and it must not be anticipated as the immediate result of the great effort which will be made immediately after the war. The spring frame must possess *wearing qualities*, rigidity, and lightness ere the majority of British manufacturers will be content to accept it as their ultimate design; and, because these things may take a little time to develop, we advocate the spring suspended saddle as a serviceable makeshift.

A Selection of Letters from Readers scattered all over the World.

Colonial Riders and American Machines.

"SPRING FRAME," Rockhampton, Queensland: "As a Colonial reader of your paper I have, of late, been interested at the amount of criticism aimed at Colonial riders and at Yankee machines.

"In your issue of August 10th, 1916, a correspondent writes: 'Possibly our makers are content to let their wares speak for themselves,' etc. That is all right; I know the British engines are really excellent, but I know also that the British manufacturer is building his frames neither to suit Colonial conditions nor to meet the Amercian rivalry.

"I hope Mr. P. C. Kerslake-Smith is not throwing insults at us Colonials in saying 'the American manufacturer is to be congratulated in making an almost foolproof machine,' and later on in saying something to the effect that the English maker caters for the intelligent rider. Does Mr. Kerslake-Smith mean to infer that intelligent riders are to be found only in England?

"My real object in writing was to say that the American maker is rapidly over-running the Australian market—and rightly so. Every day sees another Yank on the road, while the English salesman sits down and talks about 'British and Best,' 'Being Patriotic,' and so on.

"The English manufacturer is fast losing Australian trade, and he will continue to lose it so long as he turns a deaf ear to the wants of Overseas riders. Both the Yank and his agent will 'get rich quick'—simply because they offer us a machine suitable for local conditions."

An Old Machine in the Tropics.

MR. C. B. G. BARTELS, Penang, Straits Settlements: "I take the liberty to pen you a few lines—a stranger to you, though your paper is not to me, as I have been reading it for some considerable time. I have often wanted to write you, but have been so shy. During April, 1915, I was presented with a 1911 fixed engine Triumph, 3½ h.p., which had not been used for some considerable time. I am given to understand that it had passed through five or six hands, though none of its previous owners would take the trouble to run it. Being a Triumph, and knowing the machine—at least the make, which in my humble estimation is *Nulli secundus*—I jumped for joy, and had it placed on a handcart and brought home by my orderly. The rust was simply awful! I got a native local cycle repairer to take the machine to pieces and do it up. Every part had to be taken adrift practically with the help of a blow-lamp, but I had the machine in good running order within ten days. In another ten days I had attached a sidecar and had driven my wife and two children round Penang. I had, of course, to push and run with the cycle at intervals.

"I have since purchased a 1914 4 h.p. Triumph engine, and fixed it into the frame in place of the original. It has proved a great success, but, unfortunately, it also is a fixed gear.

"Everyone laughed when I fixed a sidecar to my 1911 3½ h.p., but soon others began to have sidecars fixed to similar machines.

"I have fitted a 4ft. exhaust pipe, which silences the engine considerably. Also I have repainted the machine, and added my initials to the tank. People wonder what make 'C.B.G.B.' stands for, and when I tell them the machine is a Triumph, they look at me with considerable doubt."

Two Sparks in One Cylinder.

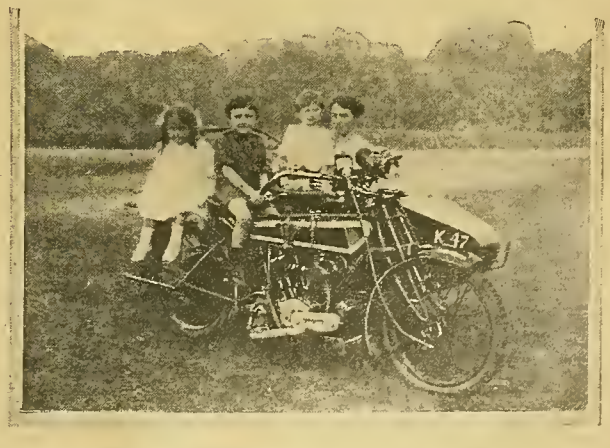
"L.W.J.D.," Nayasaland: "The usual answer that the electric current takes the easiest way is as correct as of a current of water. But we often do not know which is the easiest way for the currents, and sometimes high-tension currents take several ways, dividing themselves.

"Who has not had part of his electricity leak away, and yet got a spark, though a feebler one than he ought to have got had there been no leakage? Also when after a hundred miles riding the rider out of curiosity removes his three or four-pole plug, does he not find on all, or nearly all, poles signs of fresh sparking? He certainly will if before the riding he adjusted the poles at as even distances as possible. And if now he places the plug on the cylinder and pedals violently, will he not see two or more sparks take place simultaneously from different poles? Who doubts this should just try it. Then the man who wishes to fit two plugs in one cylinder might adjust two single pole plugs of best make a little under .5 mm., connect the two plugs by a wire, rest them on the engine, pedal hard, and as likely as not he will see both plugs spark. If he does not he might revise the distances of the points and make them .3 mm., and pedal again. He is almost sure to see both spark then. If he does not, then he need only place both in his cylinder and ride fast for, say, fifty miles, then remove the plugs, and he will see the signs of sparking on both plugs, provided both plugs were really good, and the points evenly spaced and not wider than .3 mm. Should his machine misfire with such close setting he can try the experiment with .4 mm. gaps. The starting will be a little hard, and he may have to retard the spark later on. Whoever wishes to put two plugs in one cylinder may try this for himself."

More Indian Impressions.

A reader from India says: "When first I came out to India three years ago I had a distinct prejudice against anything but British machines, and I know several other motor cyclists out here who were also of the same opinion—in fact, we used to 'slang' American-made motor bicycles; but we have all eaten our words, and are riding 7 h.p. Indians.

"I now understand that the Douglas Co. are making a more powerful machine for sidecar work, and are incorporating mechanical oiling and a chain drive in it. I hope they are putting a good clutch and plates in with the clutch pedal on the left side and brake pedal on the right (like cars). They should also braze lugs for sidecar attachments on to the cycle frame. Even if not used these would not eat anything, and would always be there if required. A point that all manufacturers should attend to is the method of fastening the handle-bars. I know of several cases in which these have become loose, half turning round, and causing the rider a nasty spill. Could not the stem and steering column have grooves cut in and a 'feather' inserted, so that it would be impossible for the stem to twist round? British makers *must* add a laminated spring frame, and they will then have a bicycle to compete with the American twin-cylinder ones. They need not bother about weight, the American machines sell like 'hot cakes' out here, and most of them weigh close on 3 cwt. We keep hoping that our British makers, such as the James, Douglas, Royal Enfield, Sunbeam, A.J.S., Lea-Francis, etc., will send us out some machines up-to-date so far as Colonial requirements are concerned. We know they are now handicapped owing to the war, but they should be getting out designs and models all ready for rapidly turning out as soon as the war is over."



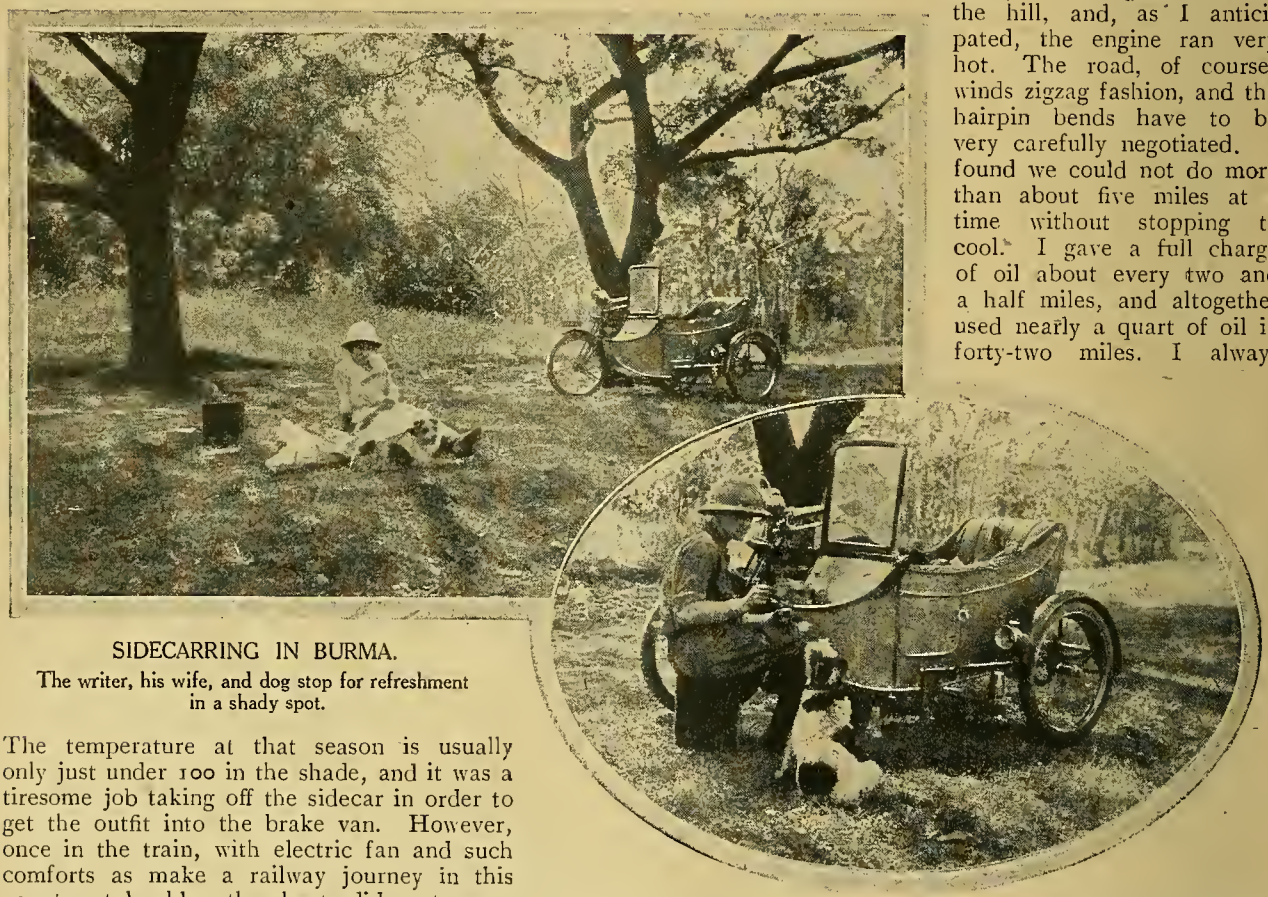
Rev. A. M. Walmsley, of Kandy, Ceylon, sends us the above pleasing photograph of his family aboard an A.J.S. outfit. On September 21st, 1916, an illustrated article, entitled "The Motor Cycle in Ceylon's Sunny Isle," appeared in these columns from his pen.

A MOTOR CYCLE IN BURMA.

A Journey to the Hills with a 4 h.p. Triumph Sidecar Outfit.

HAVING lived for over five years in this frightfully trying climate without a change of any sort, I did not feel that it was either extravagant or unpatriotic to take a fortnight's holiday last year; accordingly I obtained the necessary leave and made up my mind to journey to Maymyo, a hill station up-country, which stands about 3,600 feet above sea level. Being an enthusiast, and knowing that a road existed between Mandalay and Maymyo, I decided to try the hill-climbing powers of my Triumph.

My wife accompanied me, and we left Rangoon at midday on a Saturday for Mandalay by rail.



SIDECARRING IN BURMA.
The writer, his wife, and dog stop for refreshment in a shady spot.

The temperature at that season is usually only just under 100 in the shade, and it was a tiresome job taking off the sidecar in order to get the outfit into the brake van. However, once in the train, with electric fan and such comforts as make a railway journey in this country tolerable, the heat did not seem excessive.

The journey to Mandalay takes eighteen hours, and the country through which one passes is parched up and uninteresting. Arriving at Mandalay just after six on the Sunday morning, the first job was to attach the sidecar and fill up with petrol, then get *chota hazari* (small breakfast), and away. It took about half an hour to find the right road, and it was past eight before we really got going, and by this time it was getting very hot. The road for the first sixteen miles is almost flat, and, although the surface was bad, we did that much non-stop in fairly good time; we then had before us a climb of nearly 4,000 feet in about twenty-six miles. By this time the heat was intense, and the hill in front of us looked terrific. I stopped to cool at the foot of the hill, as I could foresee overheating troubles ahead. My sidecar is a Gloria No. 5, a heavy and luxurious affair, and we had a fair-sized hamper filled with sundry luggage strapped on the back; this, in addition to a spare tin of petrol, camera, drinks, ice, passenger, and dog, was a pretty good load for a 4 h.p. machine.

Frequent Stops to Cool the Engine.

I had Harcourt radiators on the cylinder, and used Triumph tropical grade oil. The engine was geared at 5, 7.8, and 12 to 1, and, needless to say, it was nearly all low gear work on the hill, and, as I anticipated, the engine ran very hot. The road, of course, winds zigzag fashion, and the hairpin bends have to be very carefully negotiated. I found we could not do more than about five miles at a time without stopping to cool. I gave a full charge of oil about every two and a half miles, and altogether used nearly a quart of oil in forty-two miles. I always argue that oil is cheaper than new bearings, and decarbonising is an easy enough operation, so I was not risking a seizure.

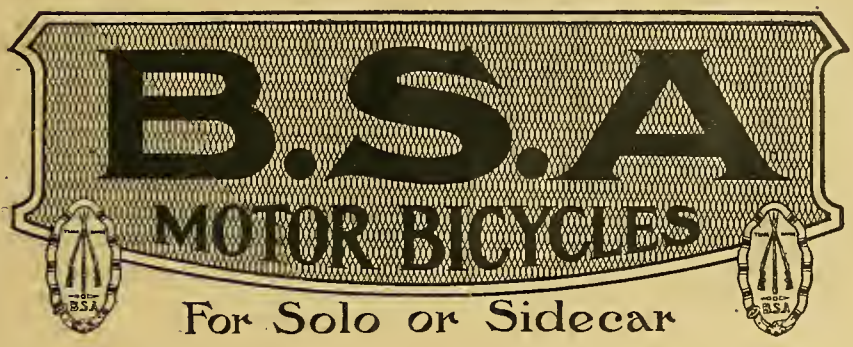
Restarting on the hill was a difficult job, the machine being a 1914 model with foot-controlled clutch. Handle-bar control, as fitted to the latest Triumphs, would have been a great advantage, and I shall certainly see that this is fitted to my next machine.

One of the many interesting things we saw on the road was a large number of wild monkeys, it being very amusing to watch them climbing about the trees in their natural state.

This road is, I believe, fairly frequently used, but, although we spent nearly five hours on it, we did not

THE MAINTENANCE

of the high standard of quality which has always distinguished B.S.A. products, and the ever increasing number of satisfied riders of B.S.A. Motor Bicycles who recommend B.S.A. machines to their friends have made the B.S.A. the most popular motor bicycle of to-day.



1917 CATALOGUE OF B.S.A. MOTOR BICYCLES NOW READY.

THE BIRMINGHAM SMALL ARMS CO. LTD., BIRMINGHAM.

B.S.A. Cylinder Oil good for all motor cycle engines.

DUNLOP EFFICIENCY

Number Three.

THE DANGER OF TOO NEW TYRES.

It is bad for a tyre to be put on the road immediately it leaves the factory.

For this reason, the Dunlop stock rooms cover a huge area, and in them are to be found tyres of all sizes maturing in an even temperature, waiting their turn to become efficient representatives of Dunlop quality.

The oldest tyre in each size always moves first and in consequence each tyre reaches the Dunlop dealer in the condition to which it has been carefully matured to give the best service.

Dunlop dealers never have tyres in stock too new—or too old. You can trust a Dunlop dealer.

A Motor Cycle in Burma.—

see another motor vehicle of any description. Such things as wayside inns, or other places where one can get a drink or a meal, are unknown in Burma. It is necessary to carry a complete set of spares, and my box contained all that could ever be required for roadside repairs or adjustments. This is where a good roomy sidecar scores: the Gloria makers provide any amount of space for tubes, belt, repair outfit, etc.

Bullock carts on the road are numerous; they are the greatest of all road nuisances; they are frequently right in the middle of the road, and the driver invariably asleep. However, I did not get baulked on any occasion when rushing extra steep inclines.

The road nearly all the way was badly exposed to the sun, and when I occasionally jumped off the saddle to ease the load it was killing work running up by the side and steering.

Breakfast—Then More Climbing.

We struck a delightfully shady spot at about the twenty-first mile where a nice cool-looking stream was running; we decided to have breakfast here. While we breakfasted the engine was, of course, cooling, and the next few miles being only moderately steep we got along in fine style without having to use low gear. This did not last for long, however, as we were less than half-way up and were soon on terrific hills again; this meant more low gear work and careful handling. Several times when the engine threatened to konk out I managed to coax it along (by means of retarding the spark and reducing the air) to a place where restarting would not be so difficult; these places were none too numerous, and occasionally I had to stop and cool in some frightful places.

The sun was blazing on us the whole time, and we soon began to gasp for another drink; we therefore stopped a bullock-cart and obtained from the Burmese occupants some water—nasty stuff, quite hot. However, a little of the "produce of Scotland" from our flask to kill the germs made it a passable drink.

As we neared our destination a marked difference could be noticed in the temperature, but it was still pretty hot—a hill station at an altitude of only 4,000 feet in this latitude is only semi-temperate, the mornings and evenings being the only times when the climate is anything like it is at home.

On arrival at Maymyo a tiffin of strawberries and cream (the first we had tasted since leaving England) was very welcome.

We were, of course, very tired, but the journey was worth all the toil; the hill was considerably more than I bargained for, or I should not have attempted it with such a load. However, we enjoyed it, and derived a great deal of benefit.

The machine is none the worse for the severe trial, and is now running as well as ever. While in Maymyo we were out morning, noon, and night, and beyond decarbonising and fitting new valve springs no other adjustments were necessary.

A Few Notes on Sidecars.

Now for a word or two on the subject of machines. I consider that even the most fastidious rider should be able to find a machine to suit him from the excellent selection of British productions available.

I have, however, one growl to make with reference to sidecar attachments. Well, we have back wheels that will drop out on loosening two nuts, and cylinders that a child could take off, but sidecars, I venture to say, cause more bad language than any back wheel or inaccessible gear box.

Naturally, when riding alone one prefers the sidecar detached, so that one can get the benefit of comfort, speed, economy, less wear and tear and easy storage; but the toil of taking off a sidecar when one has five minutes to do it in, and the temperature is over 90°, reduces the advantages very considerably.

Now what I suggest is that a sidecar should possess two legs (which could be held up with clips when riding) so arranged that by means of the legs and the wheel the sidecar will stand by itself; then the attachment should be so designed that by withdrawing four bolts the bicycle can be wheeled away, leaving the sidecar standing.

This is my one and only grievance, beyond that I consider British manufacturers do us splendidly.

R. C. SCUTT.

Concessions to Military Motor Cyclists.

Should a Revenue Tax be Necessary for a Single Run?

IT was recently suggested that motor cycles owned by men serving with the Colours abroad should be kept in condition by those at home. Already the idea has borne fruit, the writer having heard of several cases where this is being done.

There is another matter in connection with machines owned by men on military service which requires airing and is of greater importance, and that is the taxation question. Among the pleasures of a few days' leave, one of the greatest to a war-weary man is a spin along the highways. The first thing he will have to do is to find a pound for the taxation of the machine and possibly five shillings for a driving licence. This is the penalty to be paid for the pleasure of riding his machine for perhaps a couple of days or less, say twice a year according to his luck and station. It is quite reasonable to advocate a concession of some sort to men in the Army who own motor cycles, and by whom a tax has previously been paid, and who already possess driving licences. In many cases taxation was paid and a licence taken out by men last spring who have never, or at any rate very rarely, been able to use their machines.

A correspondent has made a suggestion which everyone will endorse entirely, and that is a soldier should be able to use his old driving licence, which, in consequence of military duties, he may not have been able to make use of. In addition to this, showing his permit for leave should be a sufficient proof for his exemption of taxation. There should be no difficulty in adopting such a simple procedure. It would cause the authorities no additional work, and the action would be appreciated by all, while it would be a real boon to those men whose means are slender.

OVERSEAS SECTION.

SPORTING REMINISCENCES.

DUG-OUT DEBATES.

Second-hand Market holds out.

In spite of the petrol restrictions, the sale of second-hand machines still appears good. A member of our staff who advertised his lightweight in last week's issue received several applications, and sold the machine without difficulty.

The R.A.C.'s New Name.

From March 1st the R.A.C. will be known as the "Royal Overseas Officers' Club." With the exception of members directly engaged in war work, the civilian element will be entirely eliminated, and several thousand members will have to seek hospitality elsewhere.

Sporting Reminiscences.

In this issue we publish the fifth instalment of "Sporting Reminiscences" by a veteran rider. Now that sports are suspended these chatty articles are, we are assured, very highly appreciated by those to whom competition days still exist as a pleasant memory.

Petrol Queries.

As enquiries continue to come in with regard to the petrol position, we may as well repeat the information we have already given once or twice.

The holder of a petrol ticket can continue to purchase from that ticket after March, and for so long as his allowance lasts. Thus, if he has still five gallons to draw, he can keep on drawing at the rate of half a gallon per week for ten weeks. There is no restriction which affects the using of a store of petrol on which duty has been paid, and a private owner can sell a small stock to a friend.

The new restrictions are not aimed at preventing motoring, but at saving supplies for naval and military requirements.

An Erroneous Report.

Mr. Wilfrid H. Hill, managing director of the County Chemical Co., Ltd., informs us that a paragraph appearing in several papers has caused the erroneous impression that he is about to resign his position as head of the County Chemical Co., Ltd. Mr. Hill has taken up work in connection with the National Service scheme, and is devoting the whole of his time to this for a few weeks, after which he has undertaken to give half his time. No alteration is to be made as regards his position with the above-named company.

All-British Magneto Industry.

The Irish Cyclist and Motor Cyclist informs its readers that—"For several years—in fact, since before the war—our contemporary, *The Motor Cycle* and its associated journals, have been agitating for an all-British magneto industry, and of recent months several other papers have taken it up."

Will it Come?

The prime mover on the lines of a petrol engine, having a cylinder and piston, is really an atrocious affair when viewed by the cool calculations of the mechanical mind. Yet how many have failed, hopelessly and bitterly, in attempting to evolve the only visible alternative—the internal combustion turbine. Invention is as yet in its infancy, and undoubtedly the petrol engine of to-day will prove the flintlock of to-morrow—merely a pioneer application of ignition and expansion. Turbine inventors, stick to it!

Keeping Pace with the Times.

No need for the adaptable motor cyclist to fall behind the time, as the illustration on this page, sent by Mr. W. Fleming, of Corinth Garage, 10, Stoney Lane, Birmingham, clearly shows. Mr. Fleming has ingeniously fitted his old Antoine engine with a mechanism for operating the inlet valves, which were originally automatic, thus bringing the old engine quite up-to-date.

An Antoine V-twin engine, the inlet valves of which have been converted from the automatic type to mechanically-operated valves.

Happy Islanders.

Mr. A. D. Sidgwick, a keen Guernsey motor cyclist, informs us that as yet they have no petrol restrictions in the Channel Isles.

Average Prices.

We give below the average prices of second-hand models offered for sale in the last issue of *The Motor Cycle*. Difficulty in obtaining a sufficient number of one particular model often arises, owing to the fact that many advertisers omit some of the most essential details.

Make.	Year.	H.P.	Average for last week.	Latest weekly average obtainable.
A.B.C.	1914	3½ T.T. 3-sp. s-car	—	£70

SUNBEAMS ROMP UP

Clapham Park, S.W.
24/8/16.

Dear Sirs,

Thought you'd be interested in the following remarks of one, in fact the best machine I've ever ridden—1914 3½ Sunbeam Have ridden same this last five or six months every day, wet or fine, and never had the slightest trouble. Previous to this been tearing about despatch special police midnight. In fact machine has had some of the roughest work possible and practically looks as good as new. Only last week was offered £70 for same top of Wanderers Hill, Brighton Road, a gentleman seeing me come up on top with three up, sidecar being heavy coachbuilt.

Have also several times been offered near and in one case over this amount. There seems nothing that this machine cannot do. Hill Climb (6¾ scale) five weeks back romped up with top of carburettor lost and petrol feeding very irregular.

Best wishes,
Yours faithfully,
H. V. P.

Prospective buyers are advised to have their names recorded on our Waiting List.

Catalogue and full particulars sent on application to

JOHN MARSTON, LIMITED, 11, Sunbeamland, WOLVERHAMPTON.

NOTICE

"ONE of the best compiled and informative booklets that has yet come into our possession is the brochure just issued by Messrs. J. A. Prestwich & Co., Ltd., of Northumberland Park, Tottenham, London, N., dealing with the 6 h.p. and 8 h.p. J.A.P. engines. The booklet is profusely illustrated, and shows in a perfectly clear manner the functioning of every part of the power unit, and contains a mass of valuable information which should prove of the utmost utility to the users of these popular power units. Instructions for the complete overhaul of the engine, valve timing, ignition setting, and other details form a large section of the booklet, which also contains an illustrated price list showing pictorially every part of the two-power units. It can be obtained, post free, from Messrs. Prestwich, and it should certainly be in the hands of every J.A.P. engine user."

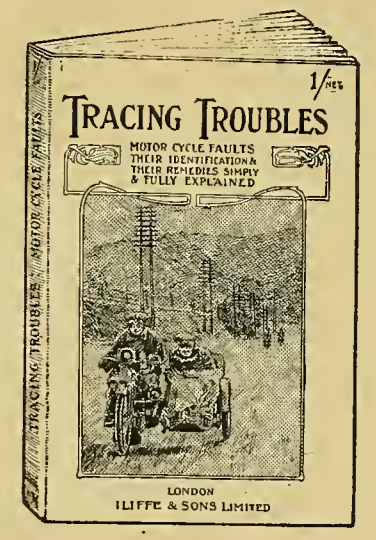
TRACING TROUBLES

MOTOR CYCLE FAULTS, THEIR IDENTIFICATION AND THEIR REMEDIES SIMPLY AND FULLY ∴ ∴ EXPLAINED ∴ ∴

Third Edition

Revised and brought up to date.



1/NET
TRACING TROUBLES
MOTOR CYCLE FAULTS THEIR IDENTIFICATION & THEIR REMEDIES SIMPLY & FULLY EXPLAINED
LONDON
ILIFFE & SONS LIMITED

THIS handy little volume deals with all the faults to which motor cycles are liable, explains how they can be easily diagnosed, and shows how they can be rectified. Every conceivable cause of trouble is dealt with, and the remedy for it carefully explained. It is written in simple language by a practical motor cyclist of long experience, and fully indexed for ease of reference.

¶ The Third Edition of this handy book for motor cyclists is now on sale.

¶ All obsolete matter has been taken out, and new matter added to bring it up to date.

¶ The Section dealing with Two-stroke Motor Cycles has been considerably enlarged and rearranged.

¶ A new section dealing with Electric Lighting Dynamos has been added.

Price 1/- net. By post, Home or Abroad, 1/2.

R10

The National War Funds.

At the week-end the principal war funds stood as follow:

The Prince of Wales's Fund (distributed £3,539,719)	£6,037,951	0	0
British Red Cross Fund	6,204,344	0	0
Tobacco Fund	125,904	0	0

Snow Driving and Driving Snow.

Those interested in bad weather motoring will find in the current issue of *The Light Car* a highly amusing article entitled "My Ideas on Snow Driving." The author was evidently "up against it" in no mean form during the recent cold snap.

Motor Cycles and how to damage them.

Many riders, having no petrol, are filling in their few leisure hours by taking their machines to pieces and tinkering with them. Judging by the effects of some people's tinkering in the way of round nuts and crossed threads, there will be some rare old crocks for sale after the war.

An Unusual Tyre Experience.

On stopping to help a novice struggling at the roadside over a tyre repair, we were informed that he had experienced four punctures—one a huge hole—in the last four miles, and that, to add to his difficulties, he had lost one of his tyre levers. Examination revealed the fact that the missing lever was actually *inside* the inner tube! It had evidently fallen into the cover during the first repair, cutting its way to the interior of the tube when the machine was ridden—hence the large hole. There was nothing for it but to make another tear to get it out. Naturally the novice felt foolish, but our sympathies were with him. Once we ourselves lost a small metal-handled penknife, ultimately finding it snugly tucked between the cover and the tube. There it had ridden for 1,000 miles before finally chafing through the tube.

Well Known in the Trade.

We regret to announce the death of Mr. T. J. Delo, a director of Messrs. Hazlewoods, Ltd., who died on Friday evening last at his residence, 7, Avondale Road, Earlsdon, Coventry.

Mentioned in Despatches.

Among the men mentioned in despatches in *The Gazette* we notice the name of Capt. A. M. Low, R.F.C., who has done valuable scientific research work for the Government.

["....."?]

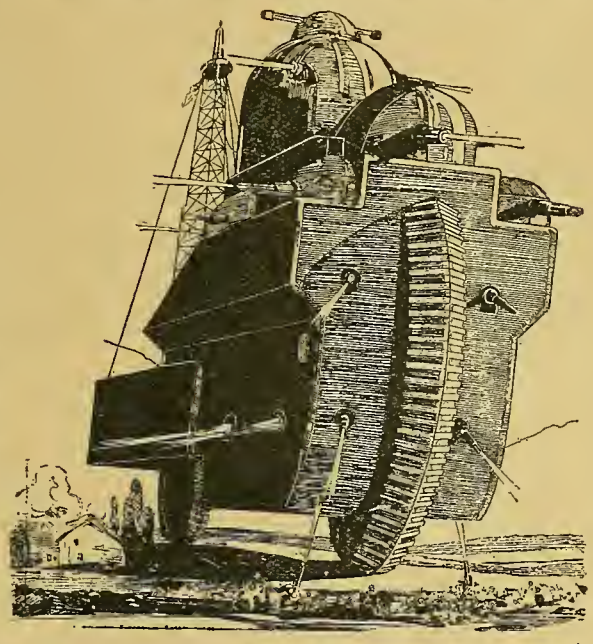
We have been amazed at the number of replies received to the simple request for a suitable title for a picture reproduced in our issue of February 15th showing a donkey gazing over a wall very dejectedly at a Bradbury motor cycle, a church occupying the background. We hope to name the winner next week. "Ancient and Modern" and "Beauty and the Beast" are common suggestions. But some are witty and original. We ought to add that many are by no means complimentary to the Petrol Control Committee.

The Cycle and Motor Trades Benevolent Fund.

The usual monthly meeting was held on February 22nd, and the treasurer's report showed a balance at the bank and in hand of £2,741 13s. 6d. A list of applications for relief, containing fifty-one names, was dealt with, and in every case but one grants were made.

Geography for the Motor Cyclist.

The double centre page map in this issue will probably reveal one or two surprising facts to home readers. It will be seen that, though enormous areas throughout the Eastern Hemisphere are rideable, few lands can compare with the British Isles for anything in the way of road surfaces. Sand, dust, potholes, and narrow roads are the common order, and our British highways and byways, though to-day battered by military traffic, would still be hard to beat from the motor cyclist's point of view.



A GERMAN CONCEPTION OF A "TANK."

No doubt the British Tanks have stirred the imagination of all people, but they must have instilled terror into the heart of the Huns to cause them to perpetrate the "nightmare" illustrated. The sketch, which originated in Germany, shows a single track leviathan, which preserves its balance by means of a gyroscope.

Lightweights and Detail Design.

There is really no excuse for the utter thoughtlessness exhibited in the minor points of design of many lightweights. In the case of one little machine we know—excellent in most respects—the task of replacing the back wheel requires two strong men, one to spring open the forks, while the other manipulates sundry small washers and clips into their respective places.

On another model an adjustment of the chains necessitates taking the machine to the local smithy to have the brake rod drawn out or shortened, no adjustment being provided. Small points of this sort weigh heavily in one's judgment when the time comes for deciding whether or not to buy another machine of the same make.

The Compact Magneto in the Flywheel.

The possibility of flywheel magnetos being used on lightweight machines in particular after the war is discussed in a leading article this week.

"The Critics" Absent.

In place of "The Critics" usual article, we publish an article this week on the subject of "Dug-out Debates"—motor cyclists' or would-be riders' debates, of course. "The Critics" will resume their criticisms next week.

Blackpool's Motor Volunteers.

The Blackpool Motor Volunteers recently spent a pleasant evening at their headquarters, when, at the invitation of the Commandant of the corps, 150 wounded soldiers were invited from the Convalescent Hospital to a "hot pot" and concert.

On Thursday last the Blackpool Volunteers were "sworn in," every man on parade taking the oath. The section appears to have been very prosperous. Several motor cyclists are still required to fill the places of those who have joined the Motor Transport.

Yet Another Name.

The Royal Overseas Officers' Club, formerly the R.A.C., has been re-christened, on account of its initials, the "Rook." No doubt the new designation originated among the late birds who come home to sleep.

Testing Substitutes.

In referring to the desirability of a road and bench test for petrol substitutes, Messrs. Archibald Vickers, Ltd., 28, King Street, Covent Garden, the vendors of Petrolior, write us setting forward one or two suggestions which they think would enable the judges to come to a fair decision. Their suggestions are:

1. Ask for a defined specification of the material offered, viz., flash point, specific gravity, and distillation chart, initial and final evaporation points.
2. Having secured these figures, purchase the material in the open market, and then, after confirming the bulk material is up to the specification given, start the tests.

Pioneer Journalism.

We always follow with keen interest the budding sporting journals of our colonies, but the following inscription to a photograph reproduction really beats us: "Pole shows the boat used to set traps on as an easy means on the water to drown the rats which dive under being caught." The reader really need not trouble about not having the illustration to go by, as it resembles a futurist effort, and might be a motor cycle hill-climb, a Turner sunset, or a trench under fire. Since the journal covers every phase of sport, art, and war, not forgetting births, deaths, and marriages, can any reader suggest what the passage means? The allusion to "rats" rather makes us think that the editor is trying to pull somebody's leg.

Riding Conditions of

AN INSTRUCTIVE GUIDE TO THE ROAD AND CLIMATIC CON

AFTER the war motor cycle manufacturers will be in search of new markets Overseas. Thousands of prospective riders scattered the world over will welcome the enterprising British manufacturer who shows interest and a desire to cater for their needs. The motor cycle is an economical vehicle of proved reliability, and it is simply a question of embodying in its specification items of practical value to suit the road and climatic conditions. The accompanying map is a guide to manufacturers in supplying the right article, based upon the demands of motor cyclists in the districts enumerated.

HOW TO READ THE MAP.

The black portions of the map mainly indicate mountain ranges. Through some of the ranges rideable passes may exist, but, owing to the large area covered, it is impossible to show isolated roads.

The shaded portions indicate regions which are as yet unsettled. For the reason above mentioned the boundaries must not be taken as exact. Certain of the shaded areas may have been crossed by pioneer riders.

The white areas indicate the present potential field of buyers of motor cycles. Here motor cycles are now in regular use; here there are chances of immediate development.

The figuring and lettering need no explanation. The figures indicate the general nature of the country; the letters indicate local conditions, and the mechanical features therefore desirable. Simply note the locality and the figure and letters nearest to it, then refer to the list.

GENERAL NATURE OF THE COUNTRY.

1. Conditions similar to the British Isles.
2. Flat country. Pot-holes.
3. Clay or mud. Riding conditions moderate in dry weather, but bad during rainy season.
4. Deep sand or dust the general order.
5. Rocky country. Water-splashes numerous. Sand and ruts.
6. Tropical to semi-temperate. Monsoons. Roads vary, but are generally narrow and dusty. By-roads bad.
7. Chiefly bush or desert tracks. Limited riding.

Eastern Hemisphere.

ALUE TO MANUFACTURERS AND MOTOR CYCLISTS ALIKE.

THINGS TO NOTE AND AN ACKNOWLEDGMENT.

Note the dark and distant places into which the military motor cycle has penetrated. This stands as a striking tribute to the efficiency and adaptability of the modern machine.

Note—manufacturers particularly—how small England is compared with the remaining portions shown white. Here we have our crowded millions, but only a few are buyers. There civilisation is scatered, but almost every man can afford to buy. And remember that the shaded area is gradually receding as civilisation creeps up.

We desire to express our thanks to Mr. T. Silver, of Quadrant fame, and to Mr. S. L. Bailey, of Douglas Bros., both of whom have toured extensively in the interests of their firms, for assistance with this map. Thanks also to our distant readers for the information their letters have conveyed. If anyone of them finds we have blacklisted his district, which he considers a motor cyclist's paradise, let him write us. His data will be carefully filed.

DESIRABLE POINTS IN DESIGN.

a. **Deep mud. Ample mudguard clearance.**

b. **Tropical. All black finish. Coachbuilt sidecars not satisfactory. Rubber goods apt to perish.**

c. **Rough country. Ample power. Good ground clearance. High magneto position. Positive drive. Spring frames or spring seat-pillars preferable. Strong sidecar frames and attachments. Strong rims and spokes.**

d. **Thinly populated. Large tanks needed. Full equipment of spares and tools.**

e. **Dust. Large tyres and wheels. Air intake preferably arranged with extension.**

g. **Adjustable air supply to suit greatly varying altitudes.**

h. **Roads good to moderate round coast.**

x. **Lightweight machines suitable for use—probably about cities.**

W. **Where motor cycles have been successfully used for military purposes.**

THE MAGNETO:

Its Function, Design, and Construction.

AT a meeting of the Coventry Engineering Society on Friday evening last, a lecture was delivered by Mr. E. A. Watson, M.Sc., on "The Magneto: Its Function, Design, and Construction." Mr. Watson is director and technical manager of the M-L Magneto Syndicate, Ltd., and showed a splendid grasp of his subject. The interest taken in the lecture was evidenced by the large audience which assembled at the Coventry Technical Institute to hear the lecture, which was to a certain extent supplementary to one delivered by Mr. A. P. Young (fully reported in *The Automobile Engineer* of March, 1915).

At the outset, the author remarked that it was possible to regard the electric spark given by a magneto or other ignition apparatus as being simply a small source of intense heat corresponding to the hot points produced by the old-fashioned ignition tube, but it was by no means certain that the function of the spark was purely thermal, as it was believed by some authorities that ignition was to some extent due to emission of ions from the electrodes, and it was stated on good authority that ignition could be produced by a brush discharge without the passage of any spark at all.

The Effect of the Spark on Engine Power.

Experiments of his own corroborated the view that the rate of propagation of the explosion, and consequently the h.p. developed by an engine, did not depend on the energy of the spark, provided the spark was of sufficient intensity to ensure ignition. If the mixture, however, were weak and the spark intensity too low, misfiring might occur, in which case the h.p. dropped off. There appeared to be little doubt that with an engine running at a normal working temperature the energy output of even the smallest magneto was ample for the purpose. Under starting conditions, however, the problem was more difficult, as it certainly required more energy to ignite a cold gas than a hot one, especially if the fuel used were of a high flash point, so as to be present in the cylinder in the form of a spray or mist rather than a vapour. Some years ago he experimented with a small influence machine which was arranged to give an oscillatory spark, *i.e.*, a spark of an extremely high temperature, but of very short duration, so that its heat content was low. For firing a gas, this was the most efficient form of spark known, but it had the peculiar property that it could be passed through an inflammable liquid or solid such as petrol, or through gunpowder, without producing ignition, merely scattering the particles of the substance on either side, due to the mechanical disruption of the discharge.

Starting in Extreme Cold.

With this form of igniter, although the engine ran perfectly in the ordinary way and when once warmed up, a very great difficulty was experienced in starting on a cold, frosty day, and this was probably due to the fact that the petrol in the engine cylinder was present in the form of a mist or spray rather than in the form of vapour. As these experiments were carried out in 1911, when the flash point of petrol was considerably lower than it was at the present time, the importance of the energy in the spark was probably greater now than at that time, and he was of opinion that the size of the magneto required by a given engine was fixed, not by the normal running conditions, but by the conditions which prevailed when the engine was being started. The position of affairs in the cylinder at the moment of ignition corresponded to the presence of a small amount of very hot gas situated at the points of the sparking plug. This hot gas parted with its heat to the surrounding mixture, thereby warming it up, and if the temperature to which the surrounding mixture was raised was sufficient this mixture in turn would be ignited, and the explosion would spread throughout the cylinder, but if not the flame would not spread and no explosion would occur. Supposing the heat zone produced by the electric discharge to be progressively diminished, it would be seen that, whereas its volume would diminish as the cube of its linear dimensions, the area of its surface would diminish as the square, so that the heat passing outwards through a unit area of surface would diminish as the linear dimensions. The smaller the zone, therefore, the less would be the temperature to which the surrounding gas was raised, and if the zone were diminished beyond a limiting size no ignition would occur, this corresponding to the minimum spark energy which would produce an explosion.

Rapid Liberation of Spark Energy.

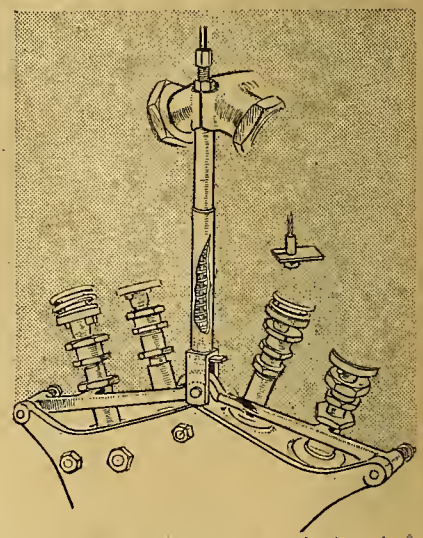
It was also obviously an advantage that the spark energy should be liberated in as short a space of time as possible, as if this liberation took an appreciable period dissipation of energy from the heat zone would be going on all the time, and the temperature would be less than if the energy had been liberated instantaneously, consequently it would require a greater total amount of energy to produce ignition.

In discussing the means by which these conditions could be best met in the construction of magnetos, he incidentally emphasised the importance of suitable cam design. It was important, he said, when a magneto was employed which had short cam segments, firstly to see that the separation of the contact points was sufficient to keep them open during an appreciable angle, and, secondly, to take care that all the sparking plugs (if the engine was a multi-cylinder one) were set to the same gap, as the presence of one plug set to a small gap might cause the next one to it in sequence to misfire.

The lecture was illustrated by a large number of lantern slides, and, in the discussion which followed, Mr. A. P. Young pointed out the advantages of the inductor type of magneto.

A J.A.P. IMPROVEMENT.

THE J.A.P. exhaust valve lifter mechanism has been considerably improved in the later models. The lifter arms are now much stiffer; the release spring is totally enclosed, so that the wire is protected. The supports of the two levers form a portion of the timing gear cover; the arms are prevented from rattling by means of a short spring; and there is a large hexagon ring on the exhaust tappet body, which is lifted by the projection on the exhaust lifter arm.

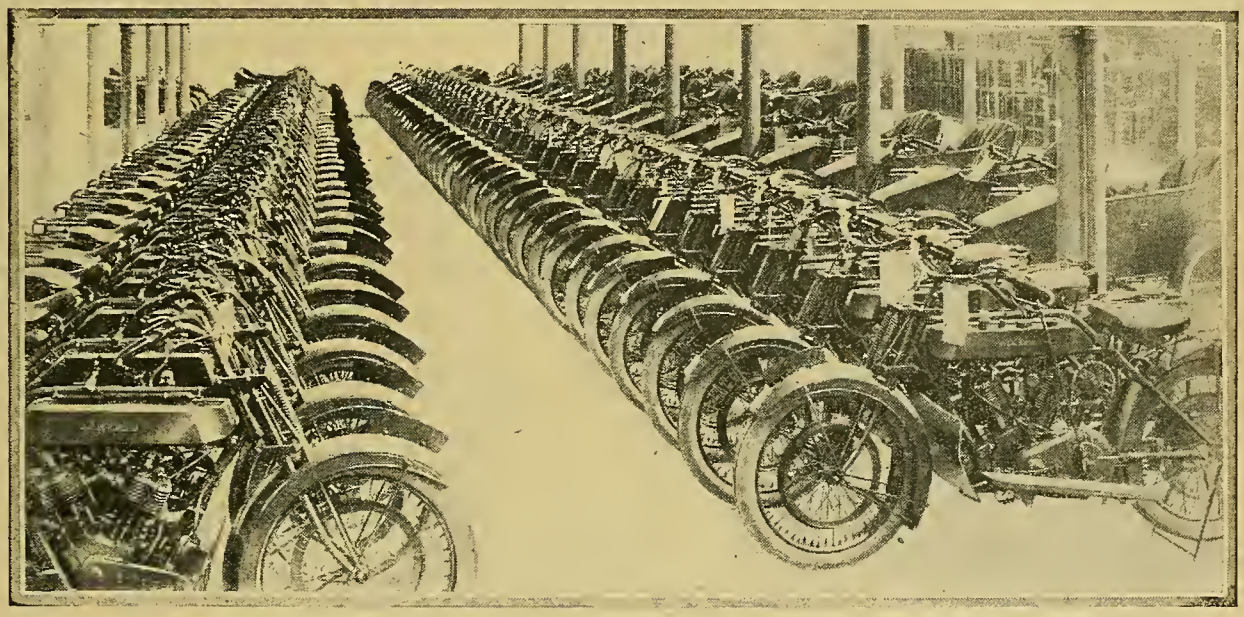


The improved valve lifting mechanism of the 5 h.p. J.A.P. engines.

Enfields for the Russian Army.

WE mentioned in our last issue that the Russian Government order for several hundred motor cycles, which has been in the air for some time past, was a week or two ago distributed among different British motor cycle manufacturers. We are now able to illustrate the first batch of machines which have been completed to that order, the product of the Enfield Cycle Co., Ltd., Redditch. All machines built for the Russian Government have to conform to a specification laid down by the military authorities. One of the points stipulated by the Russian authorities is that each machine shall have a ground clearance of not less than 6in. (manufacturers interested in Overseas markets should carefully note this fact). As a result, all the Enfield models have the Colonial type of frame.

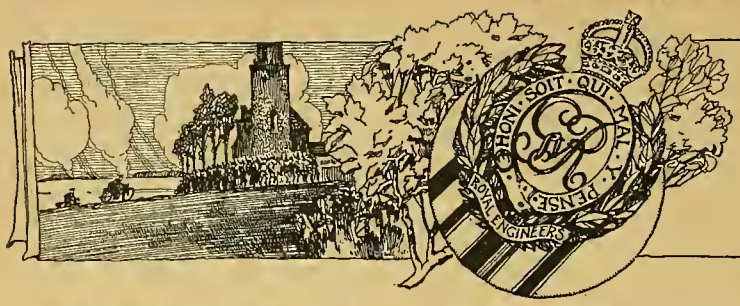
Other departures in connection with the machines illustrated are the fitting of semi-T.T. pattern handlebars with outside cables and controls in place of the V-shaped handle-bars of the Enfield with enclosed cables. There are no plated parts on these machines, the mudguards, tank, and frame being finished to match in Service green. All the Enfield solo models are fitted with 6 h.p. engines, whilst the sidecar machines have 8 h.p. engines. In general design, as will be gathered from the photograph, the machines are standard, the new type of fork with double spiral spring in front being, of course, used. The Palmer Cord tyres on the machines are 700 × 80 mm. section. The mudguards of the standard Enfield have always been of liberal dimensions and flat, so rendering them suitable for extremely muddy conditions.



Part of a large batch of 6 h.p. and 8 h.p. Enfield solo and sidecar machines completed to the order of the Russian Government.

Accessibility on the Road.

IT is odd that so few manufacturers really work out accessibility from the road as opposed to the shop point of view, writes "Road Rider." Beyond question, the integral items of the average machine fit together very comfortably when they are lying loose on a bench, or when each component is brought into the erecting shop and strewn round the fitter who faces the skeleton machine on its erecting stand. But it by no means follows that the same parts are accessible on the road or in a private garage, when a single component has to be removed from a machine in being. For example, I broke a kick starter pinion the other day, and the designer concerned, who is an exceptionally clever man, besought me to fit without delay the presentation spare which he forwarded by return, assuring me that it was only a fifteen minute job; he evidently did not wish people to see one of his machines humiliated by the push and jump start. I took him at his word, regarding him as trustworthy, and having an odd quarter of an hour tackled the job. It took me rather over an hour to get at the broken pinion, seeing that perhaps a couple of dozen nuts had to come off, and, whether by accident or design, two of the bolt heads were outside, and the hidden nuts could not be reached with any spanner in his kit or in my kit until the exhaust pipe and a few other oddments had been removed to obtain the necessary access. These two nuts multiplied the time necessary for the job by something like 600%. and his false estimate was presumably due to the fact that he had never seen a pinion refitted, except to a loose gear box. Such details will only be perfected when a special man is employed on each model of each factory to tackle all such repair and adjustment jobs against the watch, and that with the tool kit provided for customers.



MILITARY NOTES.

A TRIBUTE—MEN OF THE "TANKS."

Men of the "Tanks," we give you thanks
For all that you have done.
Through shot and shell you've stuck it well,
Your work is not all fun.

Along the Somme, midst shell and bomb,
Your mighty craft did steer;
The Hun, he flew when meeting you,
His face went pale with fear.

Ye "Tanks," roll on, for you're *très bonne*,
Your mighty strength will show
The Huns the way we'll win "The Day";
You've got them on the go.

Men of the "Tanks," we owe you thanks,
We lift our caps to you
For deeds you've done against the Hun-
And deeds you mean to do.

1st Air Mechanic R. L. Nye,
D.R., R.F.C.

IN THE MOTOR BOAT PATROL.

WE have received a very interesting letter from Chief Motor Mechanic G. Bell, who is in the Motor Boat Patrol. Bell was formerly in the employ of the New Hudson Cycle Co. for fourteen years, and competed with success in a number of competitions, including the Scottish and English Six Days Trials. His last success was in the Birmingham Club's Trial last Easter Monday, when he won a gold medal on a Harley-Davidson. He was at that time foreman over the motor cycle repair department at the Colmore depot. He mentions that the engines he is now using are just a little different from the ordinary motor cycle engines, for they have six cylinders and an open crank case with two sets of cams on the shaft, one set for "speed ahead" and the other for "astern." Another good thing which he loves as a motor cyclist is the water-cooled exhaust valve—the water actually passes down the centre of the valve. C.M.M. Bell was moved to write us from abroad on seeing the photograph of his friend, Sergt. A. Fielder, M.M.G.S., who is stationed in India.

A GRUMBLE AT GENERATORS.

WHEN we read the letter of T. P. Dixon, 2nd A.M., R.F.C., for the first time, we were surprised at one thing. He had apparently omitted to mention the great bugbear of life in France, that which is with men always, and that which all motor cyclists write about—mud. But our surmise was premature, for tucked away at the bottom of the letter was the following brief and forceful announcement: "P. and M. still wandering in mud in France." In the course of his remarks he says: "If lamp manufacturers would only make generators as good as a P. and M. bicycle, riding at night would be a pleasure—but they don't. It seems wonderful to me that motor bicycles stand up at all on these roads, as the holes in places are at least a foot and a half deep, but they don't frighten the P. and M.; it just bumps in, jumps out, and away we go."

T. P. Dixon, 2nd A.M., R.F.C., speaks glowingly of the behaviour of his P. & M. on the pot-holey roads of France.

CYLINDER BORING IN FRANCE.

SUCH delicate operations as boring cylinders on a 5in. Drummond lathe are not beyond the capabilities of M.T. men in the different workshop bases in France. At the motor cycle workshop of which Capt. Gordon I. Francis is in charge, this operation is by no means

Capt. G. I. Francis, A.S.C., M.T.

uncommon, though cylinder boring is tricky, and usually necessitates a heavy lathe mounted upon a rigid base. We recently had the pleasure of a chat with Capt. Francis, who was home on leave for a few days, and naturally, as keen motor cyclists, our conversation drifted to the design of motor cycles. He confirmed what had been stated in these columns on a previous occasion, viz., that during the present winter weather the lightweight was the more popular mount, on account of its stability and also of its ease of starting simply by paddling along the ground with the feet, but when the warmer weather and hard roads arrived the heavyweight machine again came to the front. Troubles with motor cycles are by no means absent, as the number awaiting overhaul at the different bases testifies.

Capt. Francis will be known to many of our readers, as he was a very successful rider of a Lea-Francis motor bicycle in pre-war days, obtaining medals (with his stable companion, Lt. Norman Lea, now in the R.N.A.S.) in the Scottish and English Six Days Trials and also the Colmore Cup Trial.

RAPID PROMOTION.

W. B. LITTLE, whose rapid promotion in the Army has given him an easy first over motor cyclist officers, is now Brigade Major. We shall not be astonished, in view of his consistent advancement, to see him gazetted a Colonel ere long.

ESSEX CLUBMAN IN FRANCE.

ONE of the oldest members of the Essex Motor Club is Sgt.-Maj. B. C. Siffken, who is now in France with the A.S.C., M.T. He has written us a most interesting letter on the design of Overseas mounts, and particularly those used in the war zone. The substance of Sgt.-Maj. Siffken's letter is that still a lot remains to be done before we shall have successfully tackled the problem of a real hard-work-knockabout machine for use under the worst possible conditions on thoroughly bad roads. He attributes many of the broken sidecar frames to bad brazing in the brazing shop, and incidentally remarks that as a result of this lapse the sidecar in France has not the best of names.

TRANSFERS.

A NUMBER of men in the Ambulance Service in France who are fit for general service are being sent home with a view to joining some combatant unit. Several such have written to us for advice with regard to joining one or other of the motor sections.

IN THE R.F.C.

B. ALAN HILL, the Indian, Rudge, and Humberette driver, who, at the commencement of the war, served six months in the British Red Cross Society as an ambulance driver, and on his discharge became a member of the staff of *The Motor Cycle*, is now at the Reading School of Instruction for Equipment Officers in the R.F.C.

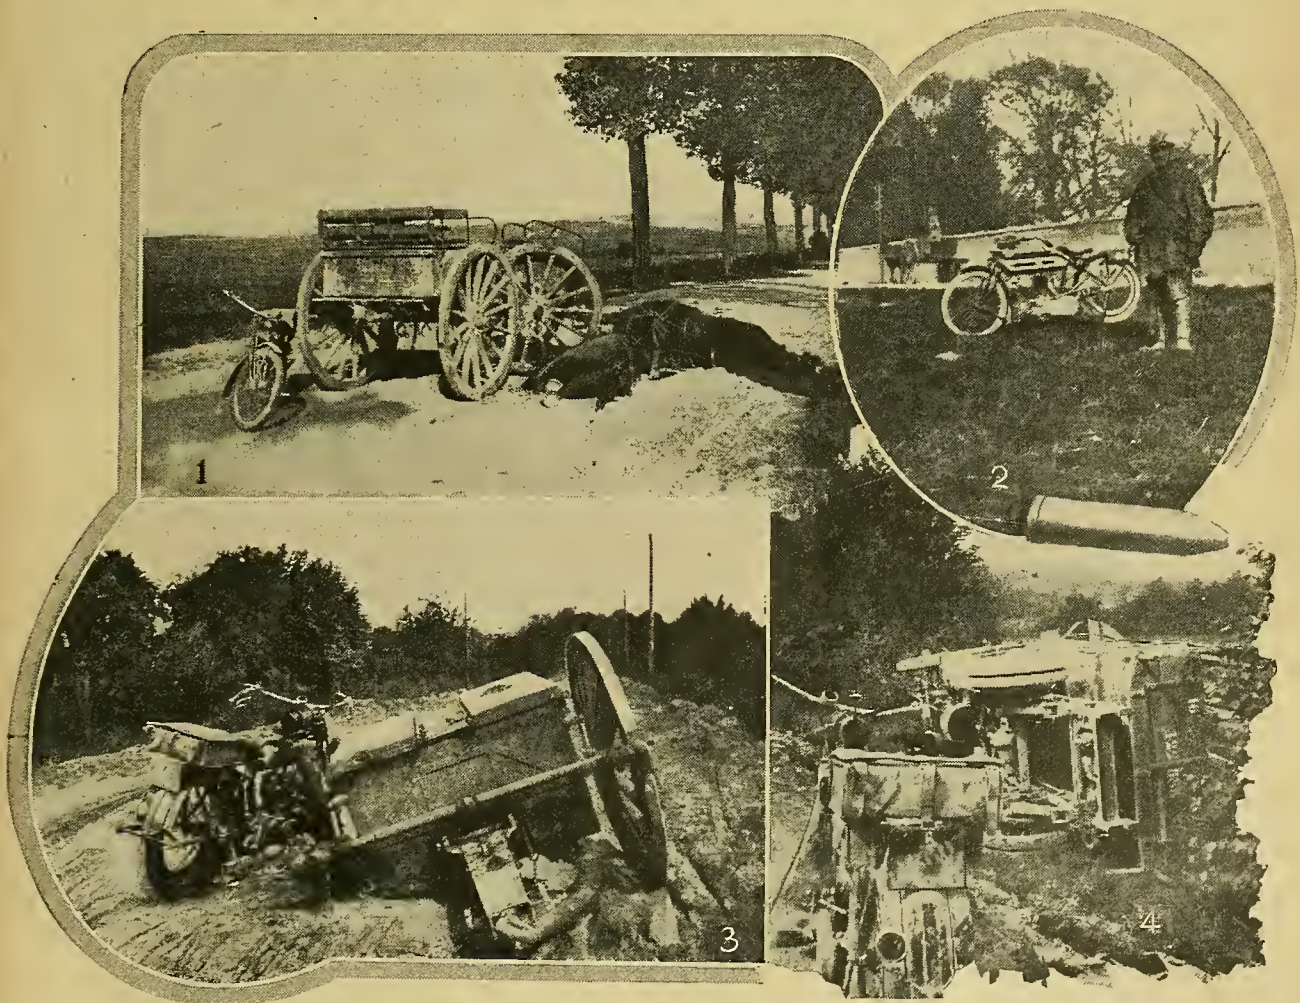
STILL FAITHFUL TO THE MOTOR BICYCLE.

WE have received an interesting letter from Lt.-Col. D. F. Nicholl, D.S.O., R.A., of which we give an extract: "One good thing about this hard weather is the delightfully dry, clean roads one gets now. I have done several little runs on one of our Triumphs lately, and find it invigorating and delightful—if one could only leave one's ears at home on the mantelpiece to keep warm! It is a great joy to feel a good engine between one's legs. I'm bound to confess that, beyond the convenience and comfort of it, being driven in a car by a mechanism-murderer is somewhat of a trial to me. *The Motor Cycle* arrives with great regularity, and is most welcome."

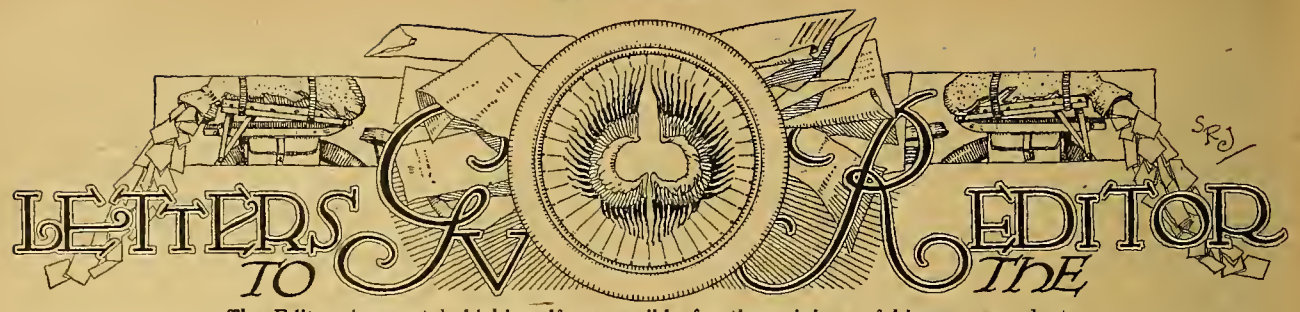
Rex Mundy, the well-known competition rider, is now in charge of an A.I.D. station near London.

IN THE TRACK OF WAR.

A Series of Exclusive Photographs taken in the Neighbourhood of Verdun, revealing in a Realistic Way the Grim Realities of War.



(1) Death lurks even on roads which look peaceful enough, for the trees do not appear to have been touched by shell fire. The picture was taken within a mile of Verdun. (2) A despatch rider of the French Army in the Champagne sector cautiously approaches an unexploded shell. (3 and 4) "Accidents" at the same "unhealthy" corner as No. 1. "All the elements," says our correspondent, "water, mud, shell fire, bad roads, holes, etc., are against the much tried motor cyclist struggling along with a machine continuously in low gear."



The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

MOTOR-ASSISTED BICYCLES.

Sir,—Advancing years compel me, a lifelong cyclist, to use a motor-assisted bicycle. Having had experience of two such, I am convinced that nothing less than 1½ h.p. is sufficient to carry me up gradients of 1 in 13. And these, which are frequently met with, are just the ones on which assistance is most needed. May I express the hope that inventors will provide for the declining strength of veteran riders? CYCLIST.

Torquay.

NAPHTHALENE BLOCKS.

Sir,—During the first week in January I journeyed to Richmond, Yorks., and back *via* Ripon—a distance of 504 miles. I used for the first time naphthalene blocks, about twice the size of a ball. Probably I used five on the whole journey. On my return I was much astonished to find no deposit on the valve caps, except a film which I rubbed, or rather wiped, off with a duster. I have known the time when I have been compelled to decarbonise at 400 miles with my 3½ h.p. Alldays-Matchless. I am not aware that there was any increase in power. There was no decrease, and I am satisfied as to the good value of naphthalene balls. The usual disclaimer. R. G. HOWARD.

CONTROL AND RATIOS OF COUNTERSHAFT GEARS.

Sir,—Is it possible that the Sturmey-Archer Co. will alter the control of their well-known gear box (which is excellent in my opinion)? I think that for foot control for touring or long distance runs on open roads it would be more convenient to have the high gear engaged when the lever is in the low position, and the low gear would be when the lever is high up. This is because the usual change (in speed) from top to middle or from middle to top would be a better reach for the foot.

I agree that for the hard D.R. conditions it is quite different. I should be glad to hear the opinions of good English riders.

Another question: I find the gears (Sturmey-Archer) too far apart for solo work; that is to say, 5.7 to 1, 8 to 1, and 13 to 1 are all right for sidecar, but for fast touring I should like something like 10, 6, and 4 to 1, the middle and top gears being close together. Is it possible to obtain pinions or box like this from the Sturmey-Archer Co.?

Paris. M. DE L. H. E. PLATEAU, E.M.

FAILURE TO START.

Sir,—I had a rather interesting experience which I think might come before your readers. It is as follows:

During the cold snap I tried to start up my Triumph (1912 three-speed). I had been riding it in the morning and it was working well. I injected spirit, and it refused to fire, which is a thing which seldom happens to me. I examined the magneto armature, but it was not stuck, then the high-tension wire, and then the plug (a four-point radiating from the pole). When horizontal on the cylinder top it sparked well; when put back the engine would not start. I emptied the carburetter, looked at the valves, timing, and everything there is to look at—called it everything but a M.C. I took the plug out, and tested it five times in the threequarters of an hour that I played with it. I washed it out with petrol, and still it would not fire in the cylinder. Then I took it out for the last time, and, as I was knocking on the ground, shifted it upwards, and saw that a drop of water had run down one of the points and established a connection which prevented it firing. When in a horizontal position the water ran back, and it fired. I removed the water and the engine started up. I may also add that during the time I had scraped and cleaned the plug points. I am not a novice, and felt very sore in being fooled by such a thing.

Sandwich. H_2O.

FORCED INDUCTION ON FLAT TWINS.

Sir,—I should like to say a few words with regard to the letter which appeared in your issue of February 22nd.

The idea of your correspondent "C.L.V.C. 2872" is very attractive, but he should not place too much faith in the fact that the idea of a.o.i. valve in the piston head and crank case induction was used in the Gnome aero engine. He should realise that, being a rotary engine, the Gnome had of necessity crank case induction and also a.o.i.v. in the piston head. The latter has long since been given up, and, in fact, the engine is out of date for all practical purposes. The inlet valve was inaccessible, and the spring lost its temper. It also had the limitations in timing which are inherent in all a.o.i. valves. M.C.B. (R.F.C.)

Oxford.

OIL CONSUMPTION.

Sir,—I notice in *The Motor Cycle* for February 22nd an account of a 200 mile run on a 3 h.p. Enfield, in which the cost of the lubricating oil is put at 6d.

I should very much like to know what quantity was used; even at the cheapest rate of purchase it seems a very meagre amount.

Discussions on petrol consumption always seem of more interest than oil consumption; but as an aid to knowledge I should very much like to hear your readers' views on my oil consumption.

I ride regularly almost every week, solo, a non-stop run of 100 miles out and 100 back through average country. My average speed works out at about 31 m.p.h. (several towns are passed through), and I have ridden several different makes and types of machines, including 3½ h.p. single, 4-5 h.p. twin, and 2¾ h.p. flat twin (the last I found could not maintain the above average).

I use one quart of oil each 100 miles. Several riders have told me I am simply wasting oil; others—old and experienced hard riders—tell me to use "all that and more."

I have never experienced a sooted plug, have never once failed to arrive dead on time, and (though not speaking as an expert) have always had a nicely running engine, which only smoked occasionally, *i.e.*, accelerating in low gear.

I may say I use the best grade of oil and of proper body.

FOUR YEARS' RIDER.

[Engines of different power vary considerably in oil consumption, and the 3 h.p. Enfield twin should be a little more economical than others of equal power, by reason of the circulating oil system, which makes repeated use of the oil, whilst the actual loss is small. On the trip in question no definite record was kept, but a very fair estimate of the amount used is threequarters of a pint or a little less (approximately 2,300 m.p.g.), a rather low consumption it is true, probably due to it being an almost continuous top gear run at reasonable speed. The oil used was purchased in bulk some time ago at about 3s. 6d. per gallon, so that 6d. will cover the cost of lubrication for the run. "Four Years' Rider" is using a lot of oil at a quart for 100 miles, and it should be possible to cut this allowance down without detriment to his engine. The average speed mentioned is high, and may account for it to some extent.—ED.]

SILENT DISCHARGE.

Sir,—I notice in your issue of February 22nd that "Ixion" mentions once again my silent discharge theory.

I have, since writing the original article, been making some further experiments, which promise to be of considerable interest. I shall hope to obtain your permission to communicate them to your readers. Unfortunately, I have but little spare time, and so the experiments, which are numerous, will take some little while to complete.

At present they point to a different cause of the trouble—they do not confirm my theory—which is simpler than the one I suggested.

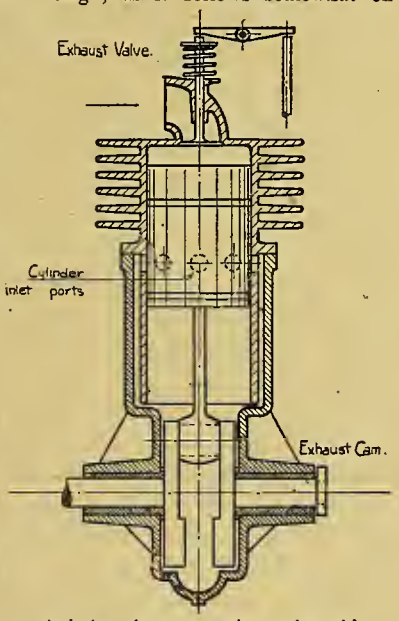
In the meantime, it would help me very much if any readers interested in the matter would *(a)* let me know what make of plug they have found satisfactory in overcoming the trouble; *(b)* let me have any notably defective plugs for testing purposes. I could not guarantee to return the plugs undamaged, as the method I am using in my experiments is one which involves considerable risk to them. If any of your readers would oblige me in this manner, it would very materially assist me in co-ordinating my results with those obtained under actual running conditions.

C. H. STEPHENSON.

[We hope to hear further from our correspondent; in the meantime, any communications sent c/o the Editor will be forwarded.—ED.]

PORT DESIGN ON TWO-STROKE ENGINES.

Sir,—I was interested in your correspondent A. H. Wilde's suggested port design, as it follows somewhat on the lines of a design I produced some four or five years ago, but lack of opportunity prevented me from testing out in practice.



A design of a two-stroke engine with overhead exhaust valve. (See F. E. Schofield's letter.)

The difference between your correspondent's design and mine is that I prefer the exhaust valve in the cylinder head, where it is in the best position for rapid cooling and also for preventing overheating of the cylinder walls and piston. Further, the annular inlet tends to maintain a more even temperature of the piston, and should prevent the annoying gumming up of the top piston ring. The cylinder casting is also more symmetrical and free from internal cores in the walls, which is conducive to better moulding and casting.

F. E. SCHOFIELD.

Sir,—I notice in your issue of February 22nd a letter from Mr. A. H. Wilde, in which he draws attention to what he terms a contradiction in my article on two-stroke engines. I still maintain that as a type two-strokes are apt to consume more petrol in proportion to their horse-power than four-stroke engines of the same cubic capacity.

Mr. Wilde gives 24% as the brake thermal efficiency of a good four-stroke engine, and 17% as the estimated brake thermal efficiency of two-strokes such as the Allon, the Radco, or the Connaught. While in no way doubting the accuracy of his 24%, I should personally have put the brake thermal efficiency of the above mentioned two-strokes at much higher than 17%. But in a matter of this nature, in which it is scarcely possible for average motor cyclists to be accurate to a digit or so, it must be a case of *quot homines, tot sententiæ*—a tag we have all learnt at school, and which we might well apply to some of the correspondence that appears in your journal.

Since Mr. Wilde has given us a description of one of the limits to "cutting away of the cylinder wall," I might mention another limit. Indiscriminate cutting away would mean that the exhaust port would be more thickly encrusted with carbon than at present. But when the exhaust port is increased by its present dimensions the cylinder would be subjected to no more distortion than is inseparable from any two-stroke engine, and the increased area of the piston exposed to the heat of the exhaust gases would give the lubricating oil scarcely any greater chance to form a carbon deposit.

I notice that "Excelsior's" statement concerning his Villiers two-stroke is criticised by "Ixion," and again in the issue of February 22nd by the rider of a Metro.

I am sure that many another motor cyclist interested in the present and the future of two-stroke engines awaits as eagerly as myself a further letter from "Excelsior."

I myself am exactly seventeen years old, and the motor cycle as a piece of compact mechanism excited my interest four years ago. I give this information in the hope that many other public school boys may take up the study of motor cycles as an instructive hobby. To the truly sporting motor cyclist the individualities of his machine mean as much as the rides to be obtained from it.

PROGRESSIVE.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—The very interesting, but somewhat inconclusive, discussion on this subject seems to be mainly carried on by gentlemen experimenting with flat twins and gentlemen who have not yet started to do so.

I do not notice much from the original makers of the flat twin, Messrs. Douglas Bros., who have commercially made these engines, which are used on motor cycles, cars, stationary workshop outfits, and the travelling Marconi outfits for Army and Navy. Perhaps this firm, which has made and sold hundreds of thousands of these engines since 1908, feels that the wholesale manner in which other firms both in England and America are abandoning single cylinders and V twins in favour of the horizontally-opposed engine may give the public an impression that, despite all the theoretical objections that have been so ably put forward in your previous issues, there must be some reason why the private owner will buy the flat twin.

As a private owner, I should briefly like to give my reasons:

1. The engine is easily started and accelerates quickly.
2. The vibration is nil.
3. The upkeep as regards tyres and belts is much less per horse-power than any other motor cycle, one, two, or four-cylinder, that I have habitually ridden.

I would just like to say a word or two in elaboration of these three points.

1. That the engine is easily started I can prove by the fact that my 3½ h.p. with sidecar had the clutch and kick-starter mechanism put out of gear early in 1916, and was never used, and indeed a clutchless gear box was substituted at the works early this year. I started out at midnight recently to a night call, primed the cylinders, and went off from cold on B.P.2. Some easy starting!

2. No vibration, or rather engine vibration. No Douglas rider needs to be convinced that this is the case. I have repeatedly seen a Marconi outfit laid on the ground with the engine running at two or three thousand revolutions, while I have carried a 2¾ h.p. outfit used for wireless Government work round a workshop by the handle with the engine running.

3. The cost as regards tyres and belts. My 3½ h.p. sidecar outfit is under-tyred, as there is not sufficient clearance between the mudguard and tyre to run larger than 26in. × 2⅜in. Even then I average over 4,000 miles with 26in. × 2¼in. passenger Hutchinsons; while in 22,000 miles driving I have bought two new belts, ⅞in. diameter, to replace the one on the machine, and two Renold's chains, a new one of which I could do with but cannot obtain.

I ride the twin opposed because I am getting old, and it gives me comfort and ease. The boys, I believe, like it because they get comfort and speed. The matter is in a nutshell.

As you are well aware, I have no financial interest in any motor concern.

CHARLES S. PATTERSON, M.B., M.R.C.S.

Sir,—Capt. Lindsay must have misunderstood my remarks (issue December 28th, 1916). If he refers back he will see that I did not state that a long induction pipe, which gets cold, improves carburation. However, I firmly believe that a long induction pipe, properly heated, would be better than a short one with no room to heat it. I have not had the experience of freezing, though I have not even lagged the induction pipe, and run on pure paraffin, which, I should think, would be more susceptible to bad carburation when cold than petrol.

Mr. H. St. V. Addenbrooke has struck the worst fault of the flat twin, *i.e.*, the timing gear rattle; but I think this could be cured by having larger stems to valves and tappets and more accurately shaped cams. R.E.C.

London, S.W.

STARTING ON ACETYLENE.

Sir,—The danger of acetylene lies in the fact that it is spontaneously explosive at 30 lb. per square inch pressure. Motor cycle compressions are much higher. Because of this property, it is illegal to store acetylene at a greater pressure than 100in. of water (3.6 lb. per square inch). Acetylene has only been employed in internal combustion engines without accident where (1) compression was less than 30 lb., (2) a "clean" explosion was not obtained (as in the case of your correspondent who complained of excessive carbonisation), or (3) it was mixed with fuel of a lower calorific value. Acetylene will also form an explosive compound with copper unless the latter is kept greased, and for that reason iron fittings are commonly used in acetylene gas lighting installations. ROBT. S. BOSWELL.

Sir,—Your correspondent Mr. Lucas has attempted to hold my name up to ridicule, and to throw not merely doubt but contempt on any opinion I may hold with regard to the use of acetylene in internal combustion engines. He did so by taking a statement of mine that there is a legal prohibition against making a mixture of oxygen and acetylene, declaring that statement to be false, and proved to be false (according to Mr. Lucas), because of the use of oxy-acetylene blow flames in engineering and other applications. He further said that he had knowledge of hundreds of internal combustion engines running on acetylene in such places as country house lighting sets, etc., and that the explosion of acetylene with air is of the same sort as that of petrol vapour or other like hydro-carbons with air.

In a letter I wrote recently I challenged him to obtain proof of his point of view on the legal question, *re* mixture of oxygen and acetylene, and I showed that the oxy-acetylene blow-through jet does not cause a mixture, in any ordinary sense, of the two gases; further I expressed the opinion that if a "mixed jet" were ever employed it could only be so under expert care, and with special control valves.

I have spent a little time recently (1) at the offices of two different acetylene commercial concerns (names sent for Editor's information) and (2) at the Home Office making enquiries.

First, let me make it quite clear that my original statement as to prohibition of making a mixture of acetylene and oxygen was only intended to be a caution to experimenters that they will be dealing with a quite specially violent explosive. It had no other bearing, and could not be read in any other sense by any ordinarily reasonable person. The only reason I bring it up again is because Mr. Lucas, with considerable discourtesy, declared that the statement showed how little worthy of consideration were any opinions I might express; and as he appears to be secretary of a commercial acetylene concern, any reader would naturally think he ought at least to know the regulations covering his own special department.

Now, sir, when I called at the Home Office to make enquiries I was taken at first to the inevitable junior. He, however, quickly grasped what I wanted, noted it on a slip of paper, disappeared for about five or ten minutes, and then asked me to come to the room of one of the senior staff engaged on acetylene and other kindred matters; this senior ranks as colonel. I stated what I wished to know: "Is there a prohibition against making a mixture of acetylene and oxygen?" "Yes," he said, "there is."

"Can you give me definite references as to it?" I asked. He had them all ready, and read various long-winded paragraphs, and then, giving me a small printed sheet, he said, "It all comes to this. First acetylene in admixture with oxygen, air, or in certain other conditions, is declared to be an explosive, so as to bring it within the general operation of the Act. Next, acetylene in these conditions is deemed to be so dangerous an explosive that it must not be made, kept, or dealt with, and so on. There are certain exceptions," he went on, "and you will see what they are."

Now these exceptions are particularly interesting in the present circumstances to me, for right in front comes the blow-pipe flame, as said my informant, pointing to the "burner" clause, showing at once the correctness of my contention in last week's letter that the oxy-acetylene flame is not, in any ordinary sense of the word, an apparatus for making a mixture of oxygen and acetylene.

Perhaps even more interesting is it to note that the Home Office considers acetylene so dangerous a substance that the prohibition extends not merely to making mixtures of *oxygen* and acetylene, but also of *air* and acetylene, unless it is in some properly contrived apparatus for burning it at once. Could there be a fuller vindication of my caution to experimenters that they have to deal with an altogether different explosion from petrol?

Now as to my enquiries at the offices of commercial concerns. In the case of No. 1 I asked to see a responsible person who knew the regulations and uses as to acetylene. When he came he told me that he did not actually know of a single engine running on acetylene, and that, broadly speaking, he would consider it a decidedly dangerous practice. I asked him about the oxy-acetylene flame. He said that only "blow-through" jets are employed.

In the case of No. 2 concern, I was met at once by one who obviously had "acetylene" off by heart in all its branches. I asked him about engines. He did not actually know of a single one regularly using acetylene, though (in common with many more) he knew it has been the subject of experiment.

"You would call the practice of using acetylene in internal combustion engines to be in merely an experimental stage, then?" I asked.

"Most decidedly," he told me.

"What is the practice with the oxy-acetylene flame?" was my next question.

"Always a blow-through jet," he said.

"Never a mixed jet," I asked.

"If you can bring out a practical mixed jet," he said, "you will bring out a thing with a very big future."

"I suppose, because of the smaller amount of gas used and the possibility of a quite small flame?"

"Exactly," said my informant.

Now, sir, it is quite clear, if we accept the above, that even the small mixing chamber, which can be used with safety in the mixed oxy-hydrogen flame, is too full of danger in the case of oxygen and acetylene to be used, in spite of its other very great advantages.

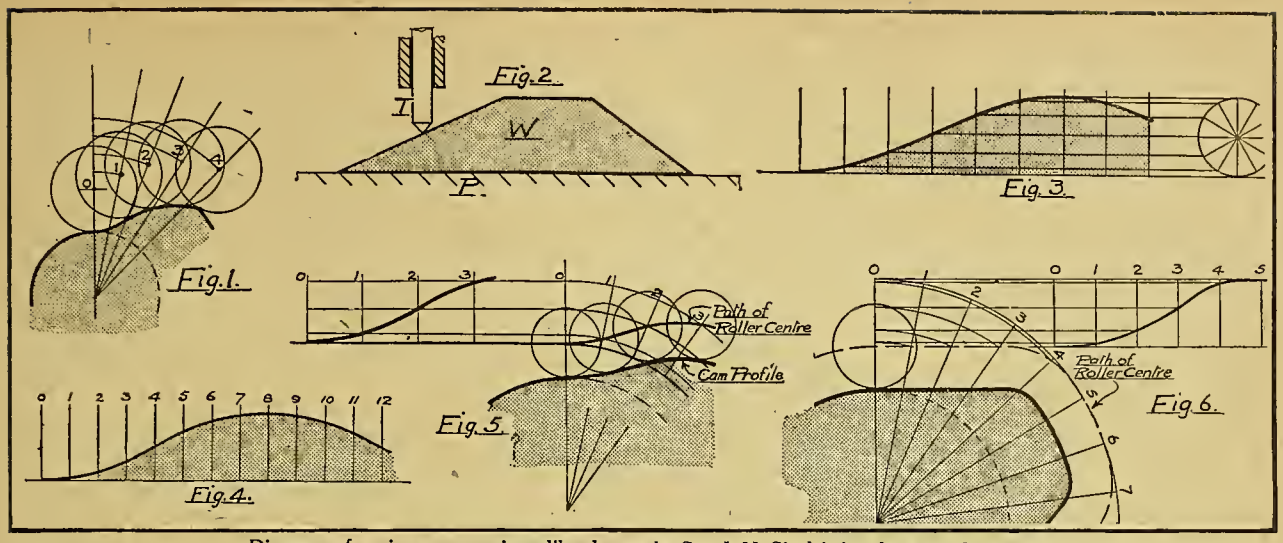
This absolutely disposes of Mr. Lucas's contention that the mixing of oxygen and acetylene is an industrial practice.

May I add one more point? Is Mr. Lucas's information *re* engines running on acetylene worth more than his information *re* the regulations of the use of acetylene? I do not at present directly call it in question, but I have seen so many country house lighting sets, and yet have never once come across an engine using acetylene; neither of my commercial informants has had better luck. Mr. Lucas spoke of "hundreds" of such engines. Can he write down one-half of one hundred? Even fifty engines which could be seen would be of very great interest to me, for I think that one could form a very fairly correct opinion as to how far experiment has reached with such a list as one's guide. It is, I suppose, hardly possible that Mr. Lucas includes in his "hundreds" certain small engines (generally running on petrol) used as accessories in acetylene gas lighting plants.

In conclusion, I do not think that any gentleman who had so aggressively attacked me, as Mr. Lucas did, will be quite content, on reading this, to leave matters without some sort of expression of regret.

I am afraid I have occupied a lot of your space, sir, but, at any rate, I have taken the trouble to clear some ground for experimenters; and to all such, who go along truly scientific lines, I say, "Here's luck." And if acetylene is is at present dangerous when merely adapted to engines not designed for it, may the time soon come when we can turn on our lamp, press a button, and glide away on the clutch!

F. C. LEES, M.A. Oxon.



Diagrams of various cam motions dilated upon by Sgt. J. H. Sinclair in a letter on this page.

CAM DESIGN.

Sir,—In the interesting article on cam design in your issue of February 1st, a mistake has been made in the diagrams showing how the cam profiles are obtained to suit any particular kind of motion. Referring to fig. 1, if 0, 1, 2 are points on the path of the roller centre as it rolls around the cam, the cam profile is the curve touching the roller circles described with 0, 1, 2 as centres. Comparing this figure with fig. 4 in the article by "A.A.S.," it will be seen that in his case the roller cuts into the cam, which is obviously wrong.

The motion produced by a cam can best be studied by drawing what may be described as the "equivalent wedge." Let T (fig. 2) be a sharp-pointed tappet, which is moved upwards and allowed to fall downwards by the wedge W as it slides along the plane surface P. Then the motion of T will obviously depend upon the shape of the wedge W. Assuming W to move along with uniform speed, then the tappet will move upwards and downwards with uniform speed if W has straight sides, as shown in fig. 2. This sort of motion is unsuitable for cams, for reasons pointed out by "A.A.S." Something more gradual in pick up and slow down is required, such as is shown in fig. 3, which illustrates a wedge which will give simple harmonic motion and also the method of getting its shape. Fig. 4 is the wedge for uniform acceleration and retardation. The heights of the various ordinates 0 to 4 are as their (position)^2 Thus if 1 is $\frac{1}{16}$in. high, 2 is $\frac{1}{16}$in. $\times 2^2$, that is $\frac{4}{16}$in. high; 3 is $\frac{1}{16}\times 3^2$, that is $\frac{9}{16}$in. high; 4 is 1in. high. From 4 to 8 the curve is similar to that from 0 to 4, but reversed.

To get the cam shape which will give any one of these motions, the corresponding wedge simply has to be wrapped around a circle, as shown in fig. 5. The curve obtained first is the path of the roller centre, as this is a convenient point to which the motion can be referred. The cam profile can then be obtained by describing a number of roller circles and drawing the curve touching them.

As "A.A.S." points out, many "tangential cams" are made because of their ease of manufacture. This is only permissible if this type of cam gives a smooth motion. Fig. 6 shows a tangential exhaust valve cam and the wedge equivalent to it; it will be seen that the pick up is all that can be desired. The slow down is rather quick, indicating that this particular cam would be improved by rounding off the corners a little more.

J. H. SINCLAIR, Sgt. M.M.G.S.
B.E.F., France.

MUD—WHAT IS ITS PROPER PLACE?

Sir,—May I join in your appeal to manufacturers to pay more attention to the important subject of mudguarding? I do not think there is much to choose between any of the modern machines I have had in this respect—they are all equally bad. I can remember riding a motor cycle in the thousand miles trials of 1903 through some of the worst weather on record, and I do not think that I succeeded in collecting anything like the amount of mud on my clothes during the whole of that period that I can accumulate during a run of fifty miles in bad weather to-day. Granted, of course, that the machine of to-day moves faster, still there has not been anything like the improvement in the mudguarding of machines that has occurred with engines and other details, and that is why I suggest that manufacturers should cease arguing about long and short strokes, flat twins, and the like, and pay a little attention to making the machine more comfortable to use.

Apart from the tendency to adhere slavishly to push bicycle ideas, where is the necessity for the mudguards always following the exact contour of the wheel? A recent experience with mudguards which persistently clogged after a slight fall of snow has convinced me that the idea is altogether wrong; in fact, they are a standing reproach to all concerned in their design, manufacture, sale, and use. If I were a motor cycle manufacturer I would set to and rig up some device in my works whereby the wheels of a machine are caused to revolve at various speeds in a bath of mud, in order in the first place to see where the mud went to. Next I would direct a blast of air of good volume on to the front of the machine to imitate the effect of the vehicle travelling, and also, as far as possible, the suction created by its passage through the air. Then I would try various forms of guards until I arrived at something which stopped the mud better than what we have at present. Then I would take the machine on the road to study the distribution of mud splashed up from the road by the impact of the wheels in the puddles.

The idea of the mudguards on all the machines I have used up to now seems to be that they shall collect the mud which is thrown off the tyre, and then carefully drip it on to other revolving parts, such as the brake rim, belt, etc., whence it can be nicely distributed over the machine and rider.

I trust that your readers will join in this crusade for better mudguards, and not wait until someone sends a properly guarded machine over from America or somewhere to arouse our manufacturers to the necessity for action in this very important matter.

D. ELYARD BROWN.

WHO SHOULD HOLD DRIVING LICENCES?

Sir,—I was rather amused at the letter of Mr. M. Hitchcock in your issue of the 8th inst. on the subject of driving licences. I have been a motorist for eleven years now and have quite failed to notice the awful fact that—to quote Mr. Hitchcock's words—"a good 75% of motor cycle and car drivers should not be granted licences at all."

I take it that your correspondent belongs to the immaculate 25%, and, of course, the great majority of us poor benighted souls who have read his effusion belong to the

bold, bad 75%. I think that Mr. Hitchcock would find if he examined 100 licences that he would not see anything like 75% endorsed, and any motorist knows that the average policeman does not love a motorist, and that he loses no opportunity to make trouble for anyone indulging in any known or unknown brand of bad driving. Why only £5 fine for omission to blow one's horn every fifty yards? Why not do the job properly and hand out a life sentence? Instead of writing such a letter, I think Mr. Hitchcock would have been better employed in inventing a mechanical horn to blow every ten yards.

In his beautiful argument of the runaway horse, why does he assume that a deaf rider necessarily rides in the middle of the road? Does his deafness prevent him from riding on the correct side?

Does Mr. Hitchcock seriously suggest that a person who is near-sighted or "partly deaf" should be refused a licence? Does he suggest, for instance, that your correspondent "M.C.S.," who has bled and suffered for his country, should be debarred the health-giving pleasure of motoring? As regards an examination for eyesight, hearing, and general intelligence, and judging by the general tone of Mr. Hitchcock's letter, I have serious doubts as to his ability to pass all three tests. I think your readers will have no doubt as to which test would "stump" him.

In conclusion, I have only to add that I am not the slightest bit blind or deaf, and have not had my licence endorsed, therefore these lines are not penned through any personal feeling in the matter.

Would Mr. Hitchcock oblige by telling me where I can see a motor cyclist drive "full speed" into a main road from a cross road? Such a sight should be worth seeing. I wonder what Mr. Hitchcock means by "full speed"?

R. E. DAIN LAWSON.

Sir,—Your correspondent, Mr. A. L. Gray, writing—rather unfeelingly—in *The Motor Cycle* of February 15th, in reply to "M.C.S.," allows his own theory to become confused with that which has still to be proved in practice.

One cannot establish a rule upon a special case, and beyond that there is no proof as to a one-eyed man's capacity for judging distance. To close one's own eye as an experiment is no test, because one is not used to the sensation.

As I also possess two eyes, I am in no better position to judge; but the fact that in sketching one almost invariably closes one eye for the purpose of judging distance is worth remembering.

If such regulations are embarked upon where are we going to stop? Surely a clear-visioned one-eyed man is not going to be deprived of that which a short-sighted man can enjoy. It is the reckless and self-confident motorist who is the danger, not the one who is fully conscious of his limitations.

MAURICE J. HELLIER (Lt.).

WHAT IS A SPRING FRAME?

Sir,—Your article on spring saddle-pillars was interesting, but, in my opinion, the fitting of a spring saddle-pillar is an insult to the makers of the saddle fitted, and only a make-shift at best.

I think it is about time that some proper definition of a "spring frame" was established by the motor press.

Devices that only protect the rider from road shock, as do the above mentioned saddle-pillars, and the so-called spring frames such as the "B.A.T." or "Edmund," hardly come within the definition of a true spring frame.

I suggest the following as a good definition of a spring frame: "A bicycle in which everything 'fore and aft,' including engine, tank, etc., is insulated from road shocks by means of springs." C. W. PIDCOCK.

BEARING PRESSURES AND LENGTH OF STROKE.

Sir,—With regard to the discussion in your columns on the subject of long *v.* short stroke engines, I am afraid that I am not in a position to go deeply into this question, from a scientific standpoint; but, in common, probably, with a large number of your readers, I judge by results; and having owned and driven several modern machines, both long and short stroke, I must say that I have always found the long stroke engine much pleasanter to drive, more powerful, and cooler running.

Your correspondent's suggestion ("H.K.P.," February 1st), that a Norton would go as well with any other bore and stroke, opens up new possibilities. Perhaps, if only one knew, Mr. Norton has already found this out; and one suspects, therefore, that this apparently guileless old gentleman advocates the long stroke principle simply with the idea of throwing other manufacturers off the scent, and preventing them from examining his engine too closely to find out where the power really does come from. Referring to Mr. Norton's article in a recent issue, it seems to me that this article is wrongly headed, as Mr. Norton does not appear to be discussing so much the advantages of long *v.* short stroke as the question of bearing pressures pure and simple. It is worthy to note, in passing, that some of the most successful motor car engines have a very much longer stroke in relation to the bore than any long stroke motor cycle engine, even the Rudge; and looking at the matter from a purely commonsense point of view, it would appear that car designers prefer to take advantage of the unquestionably higher thermal efficiency of the long stroke engine, and balance any extra stresses there may be by designing their bearings accordingly. D. ELYARD BROWN.

A HOT SIDE?

Sir,—With reference to the correspondence which has taken place on the subject of unequal distribution of heat in the walls of an air-cooled engine, I fancy that the results of some tests made under my direction on an A.B.C. engine about two months ago might prove of interest. The tests were made on a stationary set in which a standard 500 c.c. engine drives a small dynamo. The brake horse-power exerted by the engine was 4.1, and the speed 2,500 r.p.m., this being kept constant by a centrifugal governor operating on the throttle. Cooling was provided by fan blades attached to the flywheel, which directed a draught mainly on the side of the cylinders remote from the exhaust valves.

The temperatures were obtained by thermo-couples screwed under the nuts which secure the cylinder heads to the walls, one of these being under a nut close to the fan and the other on the opposite side close to the exhaust valve. These points were chosen as representing approximately the hottest part of the engine, and it may be noted that, owing to the intimate contact with the studs, the results obtained represent practically the temperature of the internal wall of the cylinder. The temperatures at the tops of the fins were not measured, but were certainly very considerably lower, it being possible to bear one's hand on the cylinder fins for a short time while the engine was running. The results were as follow:

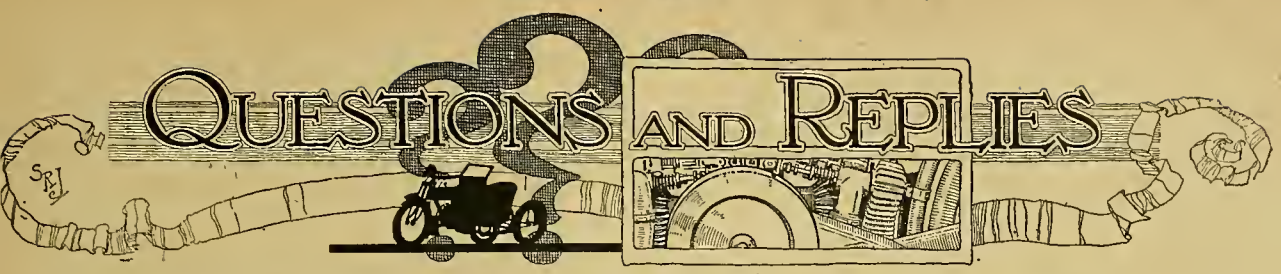
Time. Hrs.	Temp. (1). Fahr. deg.	Temp. (2). Fahr. deg.	Air Temp. Fahr. deg.
0	—	—	40
¼	219	249	47
½	217	250	53
1	219	252	60
2	221	254	60
3	221	256	60
4	221	256	60
5	221	258	60
After shutting down 2m.	298	not taken	

The engine speed corresponds to running a bicycle at 43 m.p.h. on a gear of 4½ to 1, while the power developed is about 50% more than the average required for this speed on the road. While, therefore, the cooling due to the fan was probably a little more effective than that obtained under road conditions, I am convinced that a four hours' run on the road at an average 43 m.p.h. would certainly not produce any higher temperatures on account of the less average load. The engine was well within its power capacity throughout the whole test, and was not subject to any hand adjustments from start to finish.

The temperatures are astonishingly low, and their approximate value was confirmed by attempting to melt a low temperature solder on various parts of the cylinder head. The results also show that the divergence in temperature between different parts of the engine is negligible.

No special tuning was undertaken on this engine, the set being merely one taken at random from a large number which were being tested at the same time.

I have no interest in the A.B.C. engine, but have had a very large experience of these engines on stationary sets, and give the above information as it may be useful in showing the value of the cooling arrangements on this particular design of engine. LEONARD MURPHY, M.I.E.E.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Using a Twin Magneto for a Single Cylinder.

I have a twin magneto, and I want to use it for a single-cylinder engine. Can I do this without injuring it, and shall I have to take anything out of it? —S.A.

If you remove one of the carbon brushes and the corresponding cam the magneto will work quite satisfactorily with a single-cylinder engine.

Petrol Substitutes and Starting.

I should be much obliged if you would answer the following questions. My machine is a 2¾ h.p. Douglas, and the carburetter (Amac) has warming attachment from exhaust. (1.) Could I run on pure petrol substitute? (2.) If I fitted the Binks carburetter, could I run and start up equally well on any fuel besides the Binks fuel?—C.H.G.

1.) Yes, if you start first of all with petrol or inject petrol into the cylinders. 2.) The Binks carburetter is suitable for any fuel, but you can only start on lighter spirits, such as benzene, petrol, ether, or acetylene gas.

Timing an Engine.

Would you be kind enough to describe to me (1) the process of retiming a single-cylinder? (2.) If the magneto went wrong, what parts would you advise me to attend to myself?—W.P.

1.) The engine should be timed in the following manner: *Valves.*—Set the exhaust valve to close just after the completion of the exhaust stroke. It will then commence to open when the piston is about one-seventh of the length of the stroke from the bottom of the firing stroke. The inlet should commence to open as the exhaust closes, and remain open for about one complete stroke of the piston, or while the flywheels turn through 190°. *Magneto.*—Place the piston exactly on top of the compression stroke, and connect up the magneto with the points just about to break and the ignition lever two-thirds retarded. This will mean that the explosion, when the ignition is fully retarded, will take place when the piston has travelled about .5 mm. down the firing stroke. (2.) You may adjust the platinum points when this is necessary, clean the carbon brushes and slip ring, and see that all the terminals are tight, but you cannot interfere with such points as the armature winding and the condenser, which are beyond the powers of an ordinary amateur.

Uneven Firing.

I have recently bought a Royal Enfield fixed-gear 2¾ h.p. twin, which according to registration transfer is a 1911 model. I am also told it is a Motosacoche engine. I have just lately been troubled with misfiring on back cylinder, which only occurs when running slowly, and always when I move the throttle open, and occasionally on slightly closing it. Whenever I accelerate it seems to choke the back cylinder, in spite of careful opening. The front cylinder fires well at all speeds and throttle positions. I notice the compression on the back cylinder is greater than on the front, and yet, strange to say, it does not fire so well. I have tried various plugs, with no improvement. Incidentally, I never require to retard the ignition, as it starts and runs best fully advanced. Should this be the case? If not, how shall I remedy it?—W.P.S.

We should think that the misfiring is due to some small maladjustment, possibly an unsuitable plug. Use one of good make, and preferably with single-gap electrodes. The gap at the points should be fairly large, say 1/32in.; a small gap will often cause missing. See that your valve springs are strong enough, especially the exhaust, and that the valves are closing properly. There should be about .4 mm. clearance between the valve stems and tappets. See that no air leaks exist in the induction pipe joints. It is quite usual for the magneto to require to be fully advanced all the time, but with your particular make of machine it is possible for the driving mechanism to become worn, so causing the magneto to become retarded. If this has occurred, the wear should be taken up by means of suitable packing.

"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS TANKS. A LETTER OF APPRECIATION WAS SUBSEQUENTLY RECEIVED FROM THE ARMY COUNCIL.

Trial Runs and Licences.

I possess a 3½ h.p. motor cycle, the licence of which expired on December 31st, 1916. As I anticipate selling the machine, I did not want to renew the licence. In the event of my negotiating with a probable buyer who *may not* have a motor cycle licence, and he rode the machine, could the authorities serve a summons on him or on me? Of course, I suppose I am liable if I ride the machine myself, but could they make a case of it if I merely wheeled the machine to any particular place for the purpose of a trial? I still hold a driver's licence, and I realise the probable buyer must hold one also before he rides.—P.C.R.

In the case of anyone to whom you sold your machine driving the said machine without a licence he would clearly be liable, and not you. You would only be liable if you actually rode or drove the machine; wheeling it about is not driving it. If no sale were effected, you would become liable for a licence, which must be taken out within twenty-one days.

Engine Running Hot.

My machine is a 1914 single-geared T.T. model, used in conjunction with a sporting sidecar. Every 200-250 miles I have to remove, from under the piston, carbon which is sometimes ⅜in. thick, the combustion space and top of piston being absolutely clean. I have tried all the following without a vestige of success: 1. Carburetter—I have tried various jets, petrol levels, etc. 2. I have lowered the compression nearly ⅛in. 3. I have tried different valve and ignition settings. 4. I have mixed oil with the petrol, and lubricate with Castrol. 5. Have tried various plugs. Do you think a B.S.A. carburetter would make the engine run cooler? It is the hottest running engine I have ever sampled. I have tried many. Over and under-oiling with various oils make no difference.—G.H.

The trouble is probably due to the fact that the machine is single-geared, and it is exactly what one would expect when using a single-geared machine in conjunction with a sidecar. If you had a lower gear to fall back to when the engine started knocking the trouble would be obviated to a very large extent. All you can do now, provided you cannot fit a two-speed gear, is to run with quite a low top gear, drive the machine at an easy pace, and only open the throttle when absolutely necessary.

Sparking at Contact Breaker.

I shall be greatly obliged if you can help me with the following trouble I am experiencing with my two-stroke motor cycle. (1.) A spark occurs across the points in the magneto (or rather contact breaker), and this I cannot stop. I have cleaned and adjusted the points to .4 mm., but it still continues. The machine is very difficult to start, but once started it is all right, although it is sparking in the contact breaker. Is this the cause of the difficulty in starting? There are no air leaks, and the plug is A1, also the carburetter. (2.) Why has petrol to be vaporised (or why is it vaporised) before entering the cylinder? It fires all right when petrol is injected through the release valve.—P.N.

(1.) The cause of the sparking at the contact breaker may be due to the fact that the condenser connections have broken down or are poor. Do not forget that in some magnetos the condenser connection is through the contact breaker cover. If you remove the cover when the machine is running there is excessive sparking at the contact breaker points. The difficulty in starting is probably due to the cold weather, accentuated by the bad quality of petrol now being sold. (2.) Petrol fires when injected because it evaporates. The better the vaporisation you get the more economical is your engine because you are only burning the petrol vapour, and so do not waste the liquid fuel, only a part of which is consumed.

Carburetter Adjustment.

I should be obliged if you will answer the following queries. My machine is a 1915 B.R.S. Norton, with B. and B. carburetter (pilot jet and needle-controlled main jet): (1.) I find that the pilot jet gives an easy start from cold, but gives bad slow running, and requires the extra air lever to be fully open when running. Would this be due to faulty adjustment of the needle, or is the pilot merely to be used for starting? (2.) Should I set the needle so that the extra air is kept closed all the time in cold weather? At present the engine takes an equal amount of extra air and throttle opening when running on the level.—F.P.S.

(1.) You do not say whether your carburetter is fitted simply with an easy starting jet, which has a small lever to put the jet out of action once a start has been made, or whether it is one which has an adjustable pilot jet. The former is the type usually fitted to single-cylinder machines. The jet is used only for starting, and when once the engine is running it should be turned into the off position and the speed controlled by means of the throttle only. Twins are usually fitted with the adjustable pilot jet, which is always in action, and provided in order to give even firing at slow speeds. If this type is used the pilot should be adjusted so as to give even firing at slow speeds when the main throttle is shut right off. Your trouble indicates too strong a mixture, either due to too large a pilot jet, failing to shut off the easy starting jet, or to the needle in the main jet being adjusted up too high. (2.) You should be able to give a certain amount of air at all times of the year, but with this carburetter the air is automatically controlled by the opening and closing of the throttle; thus, the extra air should not have to be placed fully open except at very high speeds. In order to be sure that you are able to get a sufficiently rich mixture for slow speeds the needle in the jet should be so adjusted that when once the engine is started a certain amount of extra air is required. We would advise you to write to the makers for a booklet on the subject of adjustment.

Position of the Sparking Plug.

Would you tell me whether the sparking plug should be over the exhaust or inlet valve on a "twin"? I have heard several opinions on the subject, but cannot rely on any.—E.H.

The sparking plug on any sort of motor bicycle engine, single or multi-cylinder, should be over the inlet valve, when it is placed in a valve cap. When the inlet valve is overhead the sparking plug is generally in a special pocket.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

READERS' REPLIES.

Butt Ended Troubles.

I have had the same trouble with butt ends as mentioned in *The Motor Cycle*, page 149, and have adopted the following tip. As a rule the butt leaks at the seam either side. What I have done is to cover the tube with thin rubber patching. Be sure the seam is covered for about one inch from the ends. Use plenty of French chalk on replacing. Tubes thus treated have been in for six months without any softening.—E. R. RISIEN.

Stopping a Blow-hole.

"W.W." (page 148) can quite easily stop the blow-hole in the aluminium crank case of his Scott with a little aluminium solder. Last year I helped to repair a flaw and crack in a friend's Scott machine. The damage was near the crank case opening, and allowed the oil to escape and the compression to be spoilt. Scrape the hole clean, and perhaps enlarge its outer end. Cut a piece of solder about the right size and lay it in the hole. With a blow-lamp make it all hot, and at the same time rub with a hot soldering iron until it adheres. No flux required.—E. J. COPE.

Tuning a Scott.

With reference to "G.G.'s" letter concerning a 3¾ h.p. Scott (*The Motor Cycle*, February 1st), I do not remember seeing any reference made to the exhaust ports being clear of carbon. Should these be choked, their restricted area would prevent the burnt gases escaping and reduce the incoming charge and also dilute it, thus causing all the symptoms of which "G.G." complains. This appears to be a very obvious remedy, but I have met many Scott owners who have overlooked this point when cleaning the engine.—C. F. BAKER (1910-1912 Scott).

Recommended Routes.

In *The Motor Cycle* of February 8th, you give a route—Dover to Wolverhampton—*via* Ongar, Harlow, Hertford, etc. I have been into Kent and back *via* Tilbury several times, but only once *via* Ware and Harlow. That piece of road, Hertford to Ongar, or *vice versa*, may look very well on a map, but one has to traverse this section to realise what a nightmare it is. There are several level crossings, and the signposts are very local in their direction, and, further, the road is in places narrow, rough, and very sinuous—eternally twisting and turning. The best route (with excellent surface) that I have discovered so far is Ongar, through Epping to Wake Arms Hotel; here turn right for Waltham Abbey, Waltham Cross. At Waltham Cross turn right again, straight through Cheshunt on the main road to Cambridge, turning left at a signpost a few miles from the Cross for Hertford. I believe this is a trifle longer than the Harlow route, but you have good straight main roads, and you travel right through Epping Forest, which at almost any time is pleasant. If I remember correctly, the distance from St. Albans to Tilbury (*via* Epping) is about fifty-four miles.—POWLAND S. SALT.

RECOMMENDED ROUTES.

WOLVERHAMPTON TO CARDIFF.—R.E.J.

Wolverhampton, Kidderminster, Worcester, Malvern, Ledbury, Ross, Monmouth, Usk, Newport, Cardiff.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

MOTOR CYCLES FOR SALE.

Alldays.

COLMORE Depots, Birmingham and Manchester, for immediate delivery of Allon 2-strokes. [0796

ALLON.—All 1917 models in stock, 36-45 gns.; exchanges and deferred payments arranged.—Maudes', 100 and 136 Gt. Portland St., London, W. Tel.: 552 Mayfair. [7387

ALLON 1916½, 2-speed, painted mauve, new oversize tyres on both wheels, special mudshield, Brampton front forks, all tools, guaranteed throughout; price £31. —Moir, Torrington House, East Molesey. [X7143

1915 Countershaft Alldays, 4h.p., 3-speed, clutch, with smart coachbuilt sidecar, and complete equipment, serviceable outfit, excellent condition throughout; bargain, 49 gns.; exchanges.—Newnham, 223, Hammersmith Rd., W. 'Phone: 80. [9052

NEW Imperial 1917 Models in stock; light tourist, 2 speeds, countershaft, 38 gns.; clutch and kick starter models, also ladies' models ready to drive away.—P. J. Evans, Controlling District Agent, John Bright St., Birmingham. [X7108

N.S.U.

1915 N.S.U. 6h.p. Twin, 2 speeds, spring frame, Bosch, all accessories, Gloria spring wheel sidecar; bargain, £45.—Blake, 216-18, Westbourne Grove. [8965

O.K.

O.K. 1916 Lightweight, run 500 miles, only guaranteed equal to new; £21.—Percy and Co., 337, Euston Rd., London. [9046

2h.p. O.K. Motor Cycle, 4-stroke, countershaft 2-speed, engine just rebushed and overhauled by makers, P. and H. lamps, mechanical horn, tyres nearly new, 140 m.p.g., extraordinarily economical and easy to start, climbs 1 in 7; owner going Front: price £16.—Seen Rider Troward's, High St., Hampstead. [8634

P. and M.

1911 2-speed P. and M., complete, lamps, etc.; £23. —Cross, Jeweller, Rotherham. [X7104

LATE 1912 P. and M., 2-speed, chain drive, handle starter, good condition, tyres Kempshall front, Avon Steel back; bargain, £35 cash.—Brindley, 973, Abbeydale Rd., Sheffield. [X7147

P. and M. Combination, 1914, with genuine P. and M. coachbuilt sidecar, head and tail lamps, horn, etc., at the unrepeatable price of 40 gns., cash only.—Layton's Garage, Bicester, Oxon. [9030

Precision.

1915 Precision, 4¼h.p., Sturmey-Archer 3-speed and clutch, Bosch latest, B. and B., lamps, horn, new tyres, recently overhauled; £30.—37, Aylesbury St., Fenny Stratford, Bletchley. (D) [X6966

Premier.

1914 Premier, 2¾h.p., in excellent condition; £25; owner called up.—Gleave, A.S.C., Seaforth Barracks. [X6826

PREMIER, 3½h.p., 1912, new condition, perfect throughout; 15 gns.—245, Hammersmith Rd., London, W. [8969

PREMIER, 1912, 3½h.p., 2 speeds; £21/10, or with sidecar £24/10.—Motor Exchange, Horton St., Halifax. [8893a

PREMIER Combination, 3½h.p., 2 speeds; seen, trial by appointment; £28.—Taylor, 25, Barlby Rd., London, W. [X7056

1914 3½h.p. Premier, 2 speeds, coachbuilt sidecar; £45; cash or easy terms.—R. E. Jones (Garages), Ltd., Swansea. [0823

PETROL Free with 1913 T.T. Premier, Brampton gear, special machine; 22 gns.—Rider Troward's, 78, High St., Hampstead. [8987

PREMIER, 1915, 3½h.p., 3 speeds, countershaft, kick starter, coachbuilt sidecar; £40; in perfect condition.—Percy and Co., 337, Euston Rd., London. [9049

Quadrant.

RIDER TROWARD'S, 78, High St., Hampstead.—Quadrant, 1913, 2-speed, perfect; 24 gns. [8995

QUADRANT, late 1914, 4½h.p., 3-speed solo, petrol starting device, splendid condition; £28.—50, Thornbill Rd., Barnsbury. [8365

QUADRANT, 3½h.p., spring forks, mag., good tyres and belt, good order, and fast; £12.—14, Dodbrooke Rd., West Norwood. [0872

PETROL Free with 1914 Quadrant combination, 3-speed, 33 gns.; solo, 29 gns.—Rider Troward, 78, High St., Hampstead. [8981

QUADRANT, 3½h.p., spring forks, D.B.T. engine, tyres, new belt, guaranteed in splendid condition; bargain, £6.—M. Hambett, 62, Newpark St., Devizes. [X7141

Radco

RADCO, 2¼h.p., late 1915, practically unused; £16, no offers.—14, Dodbrooke Rd., West Norwood. [0896

Rex

REX, latest model, 2 speeds, coach combination; £49/10.—Motor Exchange, Horton St., Halifax. [8894

REX 5h.p. Twin, 1914, free engine back hub, in first-class order and condition; £19.—Percy and Co., 337, Euston Rd., London. [9040

REX 6h.p. 1914 Coach Combination, almost new hood, screen, speedometer; £45; photo.—Holly House, Hanley Rd., Hornsey, London. [X6659

REX Twin, 5-6h.p., clutch model combination, Bosch mag., complete with coachbuilt sidecar; £14, bargain; seen by appointment.—Francis, 1a, Lausanne Rd., Hornsey, N. [8927

THE MOTOR CYCLE
ESTABLISHED IN 1903
AND FOR OVER SIX YEARS THE ONLY PAPER SOLELY DEVOTED TO THE PASTIME

Advertising and Publishing Offices:
20, Tudor Street, London, E.C.
Telegrams: "Cyclist, Fleet, London."
Telephone: 2848 City (five lines).

Editorial Offices:
Hertford Street, Coventry.

SOUTH AFRICA—Central News Agency, Ltd. PARIS—Smith's English Library, 248 Rue Rivoli.

Manufacturing Permits Extended.

PERMITS for the manufacture of new motor cycles have new been extended by the Government in a letter which was characterised by a leading manufacturer as the most straightforward and concise official document he had yet seen. In a nutshell, this letter, which is issued on behalf of the Director General of Mechanical Transport, clears a point upon which motor cycle manufacturers have long been hazy, and says in effect that if we cannot use you and your factory upon Government work, then we will not hamper your output of motor cycles. For nearly two years past, as we have pointed out on several occasions, those factories which have been unsuccessful in obtaining Government work have been gradually denuded of men and machinery and have had to surmount all sorts of obstacles in endeavouring to pursue their staple trade—this in face of Government assurances that there is no intention to close any business.

There is an important alteration, too, in the method of distributing these machines. Machines in stock which were completed prior to February 24th may be supplied without a permit, manufacturers being urged in the National interest to exercise the greatest care that they may only be placed in the hands of those who must have them for work of real importance, such as doctors, farmers, etc. It is pointed out that it is not always in the National interest that a motor cycle should be used to enable a man to get to and from his work. We are glad to see emphasised in the letter of the Director General of Mechanical Transport the need to exercise the utmost endeavours to export the whole of the motor cycles manufactured. It is pointed out that this would not only save petrol consumption in this country, but would also benefit the exchange. In future a certain number of motor cycles may be supplied to agents provided the firm is satisfied as to their *bona-fides* and that the agents will give an undertaking that they will not dispose of the machine without a permit from the Director General's department.

"The Motor Cycle"—Twopence.

COMMENCING with the issue of March 22nd, the price of *The Motor Cycle* will be increased to twopence per copy. There is, perhaps, no need for us to detail the circumstances which render such a step necessary; readers will understand that the change is made only because the existing conditions compel it.

It is also our duty to respond to the steps taken by the Government in order to bring about a reduction in the consumption of paper and set free every available ship for food and munition supplies. To the extent that our circulation may be reduced by the increase of price we shall be assisting in the direction indicated.

We have no intention to pose as ultra-patriots in the matter; our record of National service is well known. *The Motor Cycle* has willingly been pressed into the service of the country in its hour of need whenever the opportunity occurred, and we shall continue that policy.

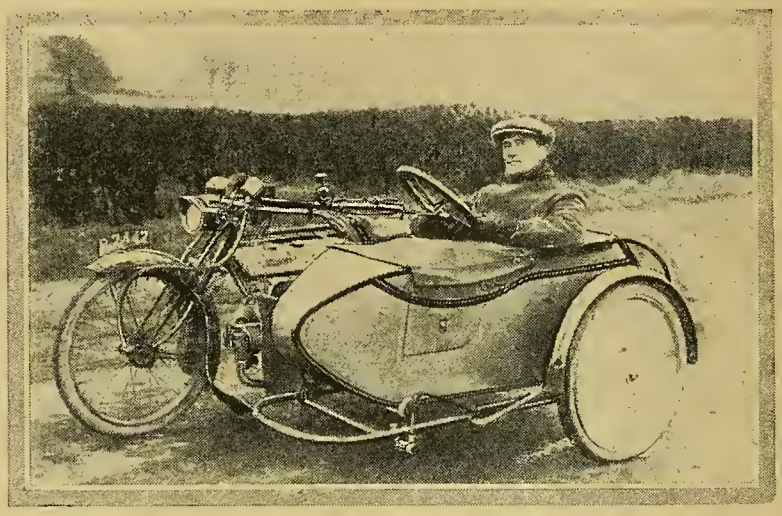
Quite apart from patriotic motives, however, it is necessary to increase the price of *The Motor Cycle* for the very simple reason that it is not possible to maintain the paper at its present high level, except at a very heavy and increasing loss, consequent upon the extraordinary increase in the cost of paper and every other commodity. We believe our readers will prefer to pay the additional penny per copy rather than see the editorial pages reduced, either in quantity or quality. It is, at all events, a test of their appreciation of and loyalty to the paper. A certain percentage may not respond to that test; others may elect to share their copy with a friend. The joint result may therefore be the retention of all our really keen and intelligent readers, and at the same time a legitimate reduction in our circulation.

An index to the advertisements in this issue will be found on the page facing the back cover.

DRIVING FROM THE SIDECAR.

A Practical Conversion for All-weather Riders.

THE idea of controlling a machine from the sidecar seat is not, of course, new. On several occasions we have illustrated machines with devices having this object, but usually tiller steering has been preferred. We believe Mr. George Brough was the first to use wheel steering for this purpose, a photograph appearing in these columns on April 20th last year showing his flat twin so converted. Mr. W. A. McKeggie, the owner of the machine now illustrated, speaks enthusiastically of his "cycle car"—composed of the flat twin Brough and an attractive Derwent sidecar—and appreciates its comfort and cleanliness, particularly in winter. He has run it for four months and finds it easy to control and steer. No doubt many who habitually use their sidecars, and are obliged to travel in all weathers, will be tempted to adopt a similar arrangement. An ordinary tiller can be used if it be found impossible to adapt a steering wheel.



A method of solving the mud and weather problem. It will be agreed that the effect is pleasing.

One of the objections to driving from the sidecar is the inaccessibility of the brakes. Complete control of these important fitments is even more essential than when driving from the saddle. On some machines the brake spindle can be carried through the sidecar body and a lever fitted inside. However, those who contemplate this method of driving had better consider the braking question first of all in conjunction with the Bowden wire catalogue; if this can be solved satisfactorily then the levers and gear change will be fairly easy to transform.

FRONT HUB DESIGN.

HOW MUD MAY BE KEPT OUT OF THE BEARINGS.

ON the subject of front hub design a correspondent, Mr. Douglas W. Grover, writes as follows:

"The last two machines I have had have both been 8 h.p. combinations, and although I have had no trouble at all with back wheel bearings, I have had continual front hub trouble. I therefore infer that the protection afforded the back hub by the brake drum on one side and the chain case on the other is what makes the difference in the life of the bearings. I think if mud can be prevented from entering the front hub it will last as long as the back one.

"My idea is to have the front forks wider and a longer spindle, but hub the same width. On the spindle a thin metal disc is placed next the cone, and then a distance-piece to make up the extra width of forks. The disc could be about the size of the lid of a boot polish tin, and might possibly be turned over at the edges similarly with advantage. The effect of this arrangement would be that the wet mud which runs down the forks all the time in wet weather would fall not on the cones as at present, but on the distance piece, and would be prevented from reaching the cones by the metal disc which would, of course, be stationary on the spindle. The idea would work especially well with that type of hub that has the cup as the external adjusting member with knock-out spindle."

This idea is a very sound one, and was, in fact, alluded to as a desirable feature in our article on "The Hubs of Motor Cycles" published on March 30th of last year. The advantage of wider forks and greater clearance was then pointed out, and a hub which embodied this special point (but without distance-pieces), viz., the Lea-Francis, was then illustrated with favourable comment. In the Lea-Francis hub the space which might be occupied by a distance-piece is occupied by a lock-nut, which enables the wheel to be removed and replaced without disturbing the adjustment of the bearing—another excellent point. Several makers adopt this lock-nut on their rear hubs, but it is most uncommon on front wheels. It is quite usual, too, for the rear hub to possess the advantage of greater clearance between fork and hub, and the forks themselves do not so readily convey mud to the centre of the wheel. On June 15th last we published a tip commonly used by despatch riders with the same end in view.

Those Auxiliary Motors.

IT is a little difficult for those of us who like 60 m.p.h., when we can get it, to believe that the big sales can ever centre round "trundling a tea-tray astern" (as a friend of mine terms motor cycling with a motor-wheel), or putting a small sea-plane starter on the flapper bracket. But simplicity, handiness, and cheapness are colossal assets, and if the economical featherweight is just about the terminus of development in any line of engineering, and therefore the last arrival of all, it often proves to be the one far off event towards which creation moves. I remember how we used to wrestle with 1¾ h.p. Minerva engines lightly clipped to the front down tube of a mildly stiffened push-bicycle, and how unspeakably obsolete they seemed when the early Excelsior came along with its 2¾ h.p. M.M.C. engine —a great lumbersome brute, with many faults, but always sweet in memory as the first real motor bicycle. Since then we have seen many attempts to produce a good lightweight, and perhaps we have not got it yet; but if the baby two-stroke is still a trifle "young," in the obnoxious sense of the word, it has at any rate proved that a good, cheap, light machine will boom the sport as nothing else could. So eventually, I suppose, quaint little jampot power units, which one will buy at gramophone dealers, and attach to push bicycles with a 4in. screwdriver and a few bands of tinfoil, may rule the motor cycling roost. Perhaps I shall just not be too old to appreciate their docility when they arrive; but as yet, thank goodness, give me something with two whopping cylinders to it, and, for choice, overhead valves.

Four-speed Gear Box Ratios.

I THINK I am already in a position to answer my own query about the best ratios for a four-speed gear box; readers may remember I expressed surprise that a certain gear box was rationed at 4½, 5½, 9½, and 13½, my surprise having reference to the long drop from third to second speeds, whereas a second ratio of about 7½ would have seemed more reasonable. The secret probably lies in the revolution capacity of the engine. The engine in question is fitted with a Claudel-Hobson automatic carburetter, which, after the manner of car carburetters, has a much longer arc of motion on its throttle lever than motor cycle carburetters possess; the arc is very nearly 180°, speaking from memory. When I first drove this machine I imagined that the throttle was wide open when it was really about half shut, and so the idea of the gear ratios never dawned on me. When I found I could open the throttle about as much again, I began to realise what the machine could do on a 9½ gear. You can twist it round at the foot of a 1 in 6 grade, and climb in a perfect frenzy of crescendo speed. With either a higher gear or a less willing engine, such a climb would be a miserable crawl by comparison. In this case, at any rate, the ratio plotting is undoubtedly justified in the interests of fast hillwork, and depends on the unusual range of the engine for its value and usefulness.

Two-stroke Piston Rings.

A CORRESPONDENT takes me to task for inferring that the top piston ring of a two-stroke engine becomes irreparably stuck in its groove as the combined result of overheating and over-oiling. He insists that under-oiling is the secondary cause, and defines under-oiling as supplying no more oil than the makers specify. If it be true that a slight increase in the oil supply will cure this ring-sticking nuisance a good many readers would employ the tip, as some engines are terrible sinners in this respect. But I am not so certain that he is right. I am a fast rider, and my normal routes are very hilly. As a consequence, when I use an engine disfigured by this particular weakness the trouble is very pronounced, and I can dogmatically assert that over-oiling will not cure it under the circumstances described, at least not with any engine I have tested. Examined theoretically, the cause seems to be that excessive heat deposits the incombustible residues of the lubricant in the groove in such quantities and at such a rate that the ring gets jammed. The oil residues would seem to be an essential factor. The heat cannot affect the dimensions of the ring and the groove so materially and so permanently as to weld the two together without the aid of heavy carbon deposits. If carbon deposits are necessary to effect the jam, a reduction in the supply of oil should delay the accumulation of deposit; an increase in the quantity of oil would lead to much heavier deposits, without an appreciable lowering of temperature! I think he is wrong.

Countershaft Gear Box Design.

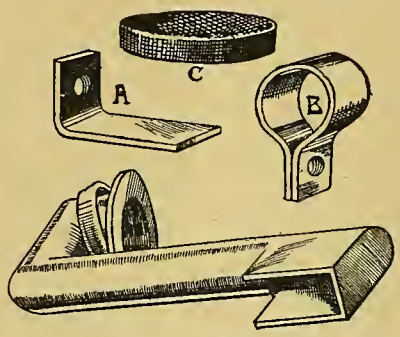
THE same correspondent invites me to pronounce on the respective merits of various gear box, clutch, and kick-starter designs. I do not possess sufficient technical knowledge, and I am in no urgent need of a libel action. As a simple-minded and somewhat disillusioned road user, my wants are few. Give me reliability all round; a gear control which is easily adjusted; a smooth clutch, with handle-bar control; and a kick-starter which does not break within three months nor stick on a dead centre at every other attempt to start, and I am satisfied. Whether the clutch is in the gear box or not I do not care a tinker's cuss. But I get exceptionally annoyed if it takes me an hour to shunt a gear box a quarter of an inch when a chain stretches; or if it is a very tricky job to recouple the controls accurately after shunting the gear box; or if the clutch reminds me of a steam tram crossing worn points; or if the kick-starter shears its teeth once a month.

A WAR TIME NECESSITY.

How a Lea-Francis was adapted to the Use of Heavy Fuel.

HAVING, like many others, fallen a victim of the Petrol Control Committee last August, I set to work to adapt my 1914 3¼ h.p. twin Lea-Francis to war conditions of motor cycling. In this particular instance it was a case of the old axiom, "Necessity is the mother of invention," for, simultaneously with the Petrol Control Committee planning out my allowance, I myself had planned a fortnight's holiday. These two schemes were not destined to work at all nicely together; and, as I had planned to ride from Glasgow to Liverpool, to tour North Wales, and then return, I soon arrived at the conclusion something must be done quickly to adapt my machine for heavy fuel. The first thing was to turn up my back numbers of *The Motor Cycle*, and here I got much valuable information on the subject.

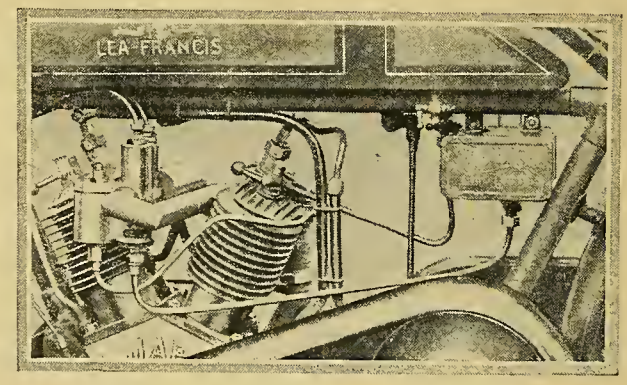
My machine was fitted with an Amac single lever carburetter, but I discarded this and fitted a Binks three-jet instrument, which I thought to be an ideal carburetter for the job, and this proved to be the case.



A, one of the four brass supports for spare petrol tank; B, clips for the tank tube; C, brass gauze "cupped," twenty-four meshes per inch, to be placed in the induction pipe. Lower sketch is the brass tubing for conveying hot air from the cylinders.

Vaporising the Fuel.

The hot air supply was first taken in hand. This was accomplished in a very neat and quick manner by taking a piece of thin brass tubing of suitable bore and cutting off three lengths at 45° and soldering together to give two right angle bends, as shown in the illustration. At the end which fits the carburetter a ring was soldered, by which the pipe is fastened to the carburetter with the screwed ring which originally held the gauze in position. The opposite end of the tube was slit longitudinally for about 2in., and the tube opened out as shown, the end being closed with a piece of sheet brass. This fits snugly between the fins at the front of the rear cylinder. When tested, it was found to act splendidly, and a big improvement was observed in the running.



From the sprocket side. A good general view of the contrivance, which is neat and unobtrusive.

Primarily, I lagged the outside by binding with asbestos cord, but afterwards I discarded this because it gave no appreciable improvement—due probably to the protected position of the tube—and made the job appear rather untidy.

Three pieces of brass gauze about twenty-four meshes to the inch were placed in the induction pipe—one at the junction of the carburetter and inlet pipe and one at each union of the induction pipe and cylinders. The latter are, of course, kept hot by the heat conducted from the cylinders. I "cupped" the gauze, as shown in sketch, and I found this held it quite safely, it being a springing fit for the tube.

The Spare Petrol Tank.

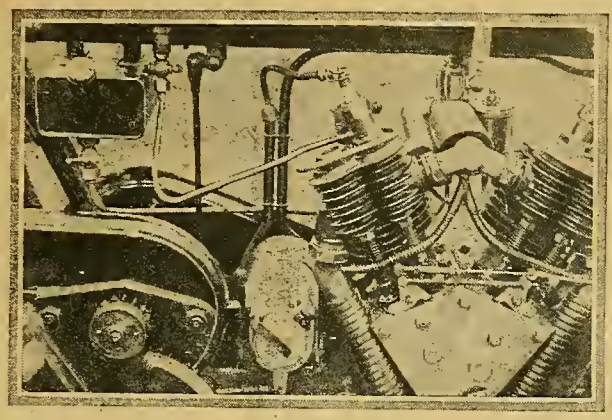
The next job was the inevitable spare petrol tank, and the first thing to be settled was the tank itself. After much hunting about the house and garage, the final choice lay between an empty quart oil tin and a large size cocoa tin. The latter proved to be the unfortunate one in this instance, and it was well soldered at all the joints to make it thoroughly petrol tight.

The next question was where to fit it, and this required some little thought. On the top tube was the obvious place, but here it seemed to mar the appearance of the machine, and eventually it was slung from the underside of the tank tube directly over the gear box. The method of suspension is shown in the sketches. A piece of brass strip was obtained $\frac{5}{8}$in. wide by $\frac{1}{16}$in. thick, and from this were bent four right-angle pieces with $\frac{3}{16}$in. holes in one side, as shown at A. These were well soldered back to back on the top of the tank, a space of $\frac{1}{8}$in. being left between the backs. Two longer pieces of the strip were taken and bent round the tank tube B, with sufficient of the ends projecting to go between the pieces soldered on the tank, and were drilled to corre-

A War Time Necessity.—

spond with the holes already in these pieces. Two $\frac{3}{16}$in. bolts and nuts and some black enamel completed the job. I was rather doubtful when I had finished it whether it would be strong enough, but hard riding for six months has removed all doubt, as it has never been touched since first fitted. The filler consists of a piece of the same tube as used for the hot air intake, soldered at 45° to the side of the tank, an ordinary cork acting as a simple and efficient stopper. The usual petrol tap and pipe were fitted, and the tank is practically invisible when I am on the machine.

My first arrangement was to use a T-piece and to conduct the petrol to the carburetter *via* the float chamber for starting. This, I found, had the disadvantage that before the petrol could reach the jets it had to displace all the heavy fuel from the float chamber and passages to the jets, which was wasteful and took a little time. I overcame this in a very simple way by connecting the heavy fuel to the float chamber in the usual way, but taking the petrol directly to the jets without touching the heavy fuel in the float chamber. The bottom cap under the jets was drilled and a union fitted, the petrol pipe going from this to the small tank. The latter, being just a few inches above the jets, gave a nice flow of petrol for starting, and it worked very successfully.



Valve side of the Lea-Francis fitted for the use of heavy fuel. The spare petrol supply is neatly tucked away beneath the rear of the main tank.

A Hot Induction Pipe.

Undoubtedly the main thing in the successful application of the heavy fuel is to supply sufficient heat for vaporisation. Thinking that an increase of temperature of my induction pipe might be beneficial, I set to work to provide the necessary heat by utilising the exhaust gases in a jacket surrounding the stump of the induction pipe and carburetter. The construction of a respectable-looking jacket in the restricted space available did not prove so easy as was at first anticipated, as it had to be built on to the induction pipe, and everything seemed as if the latter had been designed to prevent this.

However, with the dexterous use of a pair of shears and a soldering iron quite an efficient article was made. It consists of three pieces, two ends and an outer shell, and is made from tin plate. The ends were first cut and then slipped on the carburetter and induction pipe stump, the carburetter then being fastened to the induction pipe. The outer shell was bent round and soldered to each end, a few holes being bored in the one end at the carburetter for the exit of the exhaust gases.

The gases are brought from the exhaust pipes as they leave the cylinders. On the Lea-Francis flexible metallic tubing is used for the exhaust, the tubing having cast iron ends, and these ends are bored with ½in. holes to receive short pieces of iron tube, which are brazed in position. Pieces of flexible metallic tubing just slip into the ends of these tubes and convey the hot gases to a Y-piece, one limb of which is soldered into the bottom of the jacket. The Y-piece is made from brass tube, and the flexible metallic tubing just slips into the ends, no fastening of any description being used. This admits of the tubes being detached quickly, and thus easily kept clean and free from carbon. A good flow of hot gas is obtained when running, and the exterior of the jacket becomes quite hot, thus warming up the induction pipe and carburetter, and not only aiding vaporisation, but also preventing condensation.

Finally, to complete the arrangement, the fuel itself was heated; a longer fuel pipe was obtained and bent round the top of the back cylinder, as shown in the photograph. This, I think, is an advantage, as when heated the fuel vaporises much more easily. If more heat is desired the tube can be laid between the two top fins of the cylinder, but this I found to be rather excessive except when using pure paraffin, as it caused vapour locks in the pipe. With the tube in its present position the fuel and float chamber become nicely warm under running conditions.

Anyone with an aptitude for "tinkering" and who is handy with tools can with little expense adapt a machine for heavy fuel in the manner described above, and thus become practically independent of petrol.

Finally, I might add that all the fitments have now been well tried, having been in continuous use for over six months, working most successfully without giving any trouble, and proving to be well worth the energy expended in fitting. R.

TEN YEARS AGO.

A READER asks on March 16th, 1907, Who will be the first manufacturer to produce a 3½ h.p. motor cycle with spring forks, magneto, change-speed gear, first-class tyres, and all up-to-date improvements, including essential "extras," for £25? It is a long time coming. At that date a discussion was proceeding on the subject of belt *v.* chain transmission, which is still a topic of debate.

In the same issue it was stated that an £80 entrance fee was required from all competitors entering the Pekin-Paris "drive" of 8,750 miles. The Contal and Werner were the only motor cycle entries up to the time of the announcement.

The question as to whether deafness should be a bar to a man obtaining a driving licence was to the front at that time—even as it is to-day.

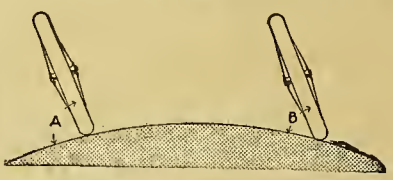
AVOIDING SKIDS.

THE CAUSES OF SIDESLIP AND HOW THEY MAY BE MINIMISED.

MOTOR cyclists use their machines in all weathers, no matter how bad the roads may be. This is especially true of our gallant despatch riders whose duties are so urgent that they brook no delay. A few hints which may enable riders to avoid sideslip will, therefore, not be out of place.

The three great factors in skidding are, firstly and foremost, the nerves of the rider; secondly, the natural stability of the machine, or in some machines the lack of it; and lastly, the surface of the road and quality of the mud. This last, of course, is beyond our control, and our efforts in the avoidance of skids must be confined to the other two headings of which the machine's shortcomings are the more easily rectified.

The bad weather stability of a two-wheeled single track vehicle, as a motor cycle, is solely dependent upon weight distribution, relatively to the front and rear wheels. In most modern machines this important subject has had full attention from the makers, except in one or two cases where it would seem that the designers are either riders of the butterfly type or possess the ability to hold up any machine on any surface, as do a few who served their novitiate on the high-framed monstrosities of nine or ten years ago.



Angles of wheels on a cambered road, showing how the tendency to skid is accentuated when a corner is taken wide.

Distorted Frames.

The owner of a machine found wanting in the matter of stability should first look to his frame, more especially so if he bought the machine second-hand and does not know its past history. It may have been pulling a heavy sidecar badly lined up, previous to coming into his hands, in which case the frame is almost sure to be distorted, very slightly perhaps, but nevertheless sufficient to throw one of the wheels out of its vertical plane and also, possibly, its track. The most likely point of distortion is the front forks, and where these are faulty the wheel will be noticeably out of centre. Unless the owner is an experienced mechanic, in which case he will need no advice, it will be necessary to send the job to a reliable firm specialising in this class of work.

Bearing Adjustment.

Make sure the wheel bearings are properly adjusted, and should it be found impossible to take up the play in either wheel, renew the cone at once, as these little items are cheaper than skids, and the trouble of fitting is time well spent. While examining the bearings see that the rear wheel has not been pulled over by the transmission, as sometimes happens on chain-driven machines possessing a weak design of adjustment to the rear chain. Wheels, if badly out of truth, must be trued up, but a slight failing in this respect may be ignored, as most rims suffer more or less in a season's use. Play in the steering head must be corrected, as the nucleus of a wobble, which finally develops into a side-slip, may be frequently traced to this cause. In tightening the head take care that the steering is not left too stiff, since such a state of affairs makes the correction of a skid a very difficult matter.

A low saddle position is essential to steadiness, and if the owner intends keeping his mount for, say, two seasons, the cutting down of a high frame is well worth the expense incurred. The substitution of T.T. bars in place of the more comfortable upturned type will often work wonders as regards control on grease. Their superiority lies in the fact that one's weight is supported more or less equally between the front and rear wheels, and the use of the bottom bracket footrests, in place of the forward pair, creates a feeling of greater confidence in one's ability to correct a slip if necessary.

Belt-driven machines, as a rule, show less tendency towards skidding than chain-driven types, while two-strokes and small twins are superior to single-cylinders. It must not be inferred that a hard and fast rule may be drawn between types which skid and those that do not. There are several riders of chain-driven single-cylinders who have never had a side-slip, and, on the other hand, a skid on a light two-stroke is not a thing unheard of; but in these instances the personal element undoubtedly counts for a great deal.

How to Ride.

The nerves of the rider, as previously asserted, play an important part in the determination as to whether or not the machine retains the vertical on a slippery road. We all know the man who can ride over tramlines thick with grease at a reckless rate on a thumping single without mishap, and also the nervous rider who crawls along on a two-stroke with feet astride slithering all over the road. The majority of us probably are in a class midway between the two.

It is a great mistake to proceed with eyes glued to the front wheel—a habit with some—on a treacherous surface. Look straight ahead, hold the body loosely, and let the grip on the handle-bars be just sufficiently firm to convince one that one is master of the machine, without keeping the muscles of the hand unduly taut. Endeavour to ride as though the mud were non-existent and avoid sudden swerves. While the machine is proceeding steadily in a straight line a skid is practically impossible, but immediately the direction is changed several conflicting *forces* are set up and the chances of slip increased tenfold. A speed of about fifteen miles per hour will be found the safest for the average

Avoiding Skids.—

rider. On a soft surface the unforeseen necessity for sudden braking at anything above this speed is sure to end in disaster, and a careful driver should be always in a position to pull up fairly quickly should emergency demand. Slithering the feet along the ground is unquestionably asking for trouble.

The Use of the Brakes.

It should be superfluous to state that braking is undesirable on a slippery surface. If you must brake, apply the rear one very carefully and release immediately the wheel is felt to lose its grip of the road. On no account make use of the front fitment. It is decidedly preferable to lock the back wheel and

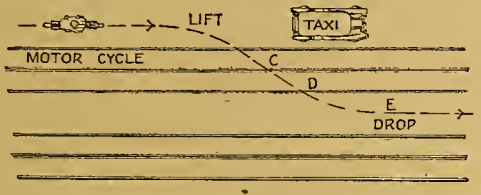


Diagram showing where to lift and release the exhaust valve lifter when crossing greasy tramlines.

experience a skid than to risk a spill from the front wheel brake. A back wheel skid is to a certain extent protracted and controllable, but that from the front wheel is unpleasantly sudden and utterly ungovernable, permitting the unfortunate rider no time to select a soft spot on which to fall. Tramlines are undoubtedly responsible for seventy per cent. of a motor cyclist's spills, and those with a centre rail between stone setts are the worst offenders. When slow traffic forces one on to this portion of the road the clutch should be slipped while actually crossing the metals. On a bicycle minus a clutch the exhaust lifter may be used provided it is not dropped until the original direction of travel is resumed.

Roads and Tyres.

Stone setts and wood blocks if coated with a layer of churned-up mud will instill misgivings in the best of us, but so long as violent changes of direction can be avoided a safe passage is assured. A wet surface, as distinct from thick mud, need occasion little anxiety, as the wheels are in no way prevented from obtaining a good grip on the road.

As regards tyres, we have one set of riders who maintain that the tyres should he soft in order to have a large effective gripping surface, and their opponents who aver that a hard tyre obtains a better grip on account of its cutting through the mud to the road beneath. The writer compromises by leaving the rear one at its normal inflation and letting down the front ever so slightly when mud plugging has to be done, and his side-slips, recently at any rate, have been comparatively few.

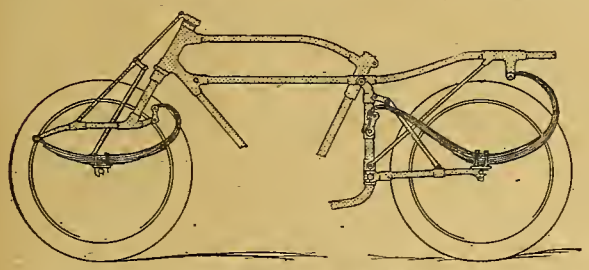
It is hoped that no self-respecting motor cyclist will take out a pillion passenger in muddy weather, but should he be overtaken by a storm and find it necessary to return over roads in a greasy condition, he must insist upon the passenger sitting close up, and, having adopted a comfortable position, refraining from any changes whatever without warning to the pilot.

CLUCATOS.

TWO MORE SPRING FRAMES.

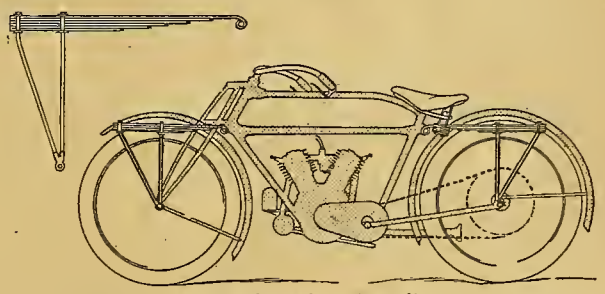
Bringing the Number of Designs reviewed subsequent to our Campaign to Ninety.

TWO more spring frame designs must be added to those published in *The Motor Cycle*—already a long list. The first is the invention of Mr. C. T. Stone, of Caerphilly, near Cardiff, and briefly it consists in prolonging a double tube, which passes from the tread below the tank, to the rear in the form of a carrier. This extension, strengthened by means of light tubes and supported by curved leaf springs, carries the weight of the rear part of the machine. The springs are capable of swivelling at the rear axle, and their forward ends are supported



A Welsh design of spring frame.

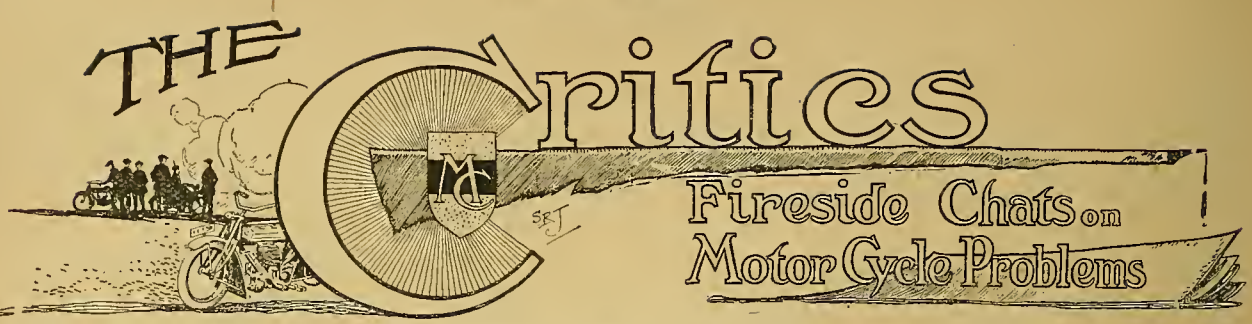
by shackles attached to the rearmost of the two down tubes from the saddle. The front forks are not covered by the patent (No. 102,392, 1916), and are self-explanatory.



A spring frame from Australia.

The second design has been sent to us from Newcastle, N.S.W., Australia, by Mr. W. G. Shellshear, M.B. The springs, which are, of course, in pairs, are carried by triangulated pieces attached to the axles, thus the springing is from the wheels to the frame instead of *vice versa* as usual. The inventor tells us that he has tried the springing on the front wheel and finds the extra weight on the wheel an advantage rather than not. The springing depends, of course, upon lessening the angle between the points A and B.

The rear parts of both these frames appear to us to be somewhat lacking in lateral rigidity as at present shown, but this fault may be overcome in the final designs.



THE fire was comforting. Silence reigned within. The Manufacturer was dosing. The D.R. was dreaming of peace, abundant petrol, and—other things. The Journalist, obsessed by thoughts of heavy fuels, was wondering whether he could run his fountain pen more economically on Jeyes fluid than on ink.

"*I* think," announced the Novice with disquieting suddenness, "that manufacturers ought to wake up."

The member of the trade sat up with a start.

"Take the size of wheels as an example," pursued the Novice, with the supercilious confidence begotten of second-hand information. "Why not heed the insistent appeals of practical riders for 28in. × 3in. wheels and tyres? It does not necessitate altering plant. It would fill a long felt want—especially Overseas. It could be done without demur or delay. Why not, then?" And the Novice stroked his waistcoat with the confidence of a city mayor who has just announced that the drains were bad—a fact painfully evident to everyone.

"What makes you think that these huge wheels and tyres are preferable?" demanded the Manufacturer, by way of a cross-question.

With mayoral confidence the Novice expanded amidship. "Ask any man who has ridden a big Yank!" was his simple retort. "To-day I was nearly shaken to death over the pot-holes——"

Large Wheels for Large Machines.

"Just so! Exactly! Precisely what I knew you would say," stated the Manufacturer triumphantly. "The big Yank—certainly, because the 28in. × 3in. is essentially the tyre for a heavy, powerful machine. But we are not talking about big Yanks. You refer to the moderate British production, and I can give you several reasons why the British manufacturer jibs at 28in. × 3in. wheels and tyres. To begin with, they are apt to skid abominably on bad roads, which is easy to understand. Immediately the pattern has disappeared from the tread, the tyre presents merely a large, flabby surface to the road, which does not cut through the grease."

"My experience is that, with these large wheels, one does not wear out the tread," said the D.R. "The tyre goes at the skirt, or is ruined by cuts before the tread is worn out."

"That depends entirely on the nature of one's riding," replied the Manufacturer. "I guarantee that if you take a dozen Indians on the road you will find at least nine of them with treads worn to the skidding point—canvas still perfect. There are other points. Firstly, everyone demands a low price machine, and 28×3in. tyres add considerably to the cost——"

"Initial cost, yes," drawled the Journalist. "But at the end of the year the 28in. wheel is the cheaper. Go on. Turn the shells out."

"Secondly," pursued the Manufacturer of Munitions, "you want to be able to obtain a cover anywhere. You cannot do this if 28×3in. is your size."

"Ye gods!" interposed the D.R.; "but you would be able to if that size became commonly used, which is what we suggest. Let's have the heavy artillery."

The Shell Maker held up a restraining hand. "All right," he agreed. He turned to the Journalist. "Have any of you any considerable experience of 28×3in. tyres?"

The Journalist removed his pipe, and looked somewhat cornered. "Yes," he confessed, rather reluctantly. "I can't say that I was particularly struck by the 28×3in."

"Why not?" It was one of those simple questions that demand an adequate answer.

Several reasons. Ridden at moderate speeds, and when in a flabby condition, it is topping, but in the trials we had to blind over narrow roads at any speed up to sixty. Doing this on a 3in. tyre, one is haunted by the thought that the tyre might puncture or pull off the rim, which would probably mean a head-first collision with one of the adjacent walls. The 3in. section is ideal for pottering over bad roads, but it is a nightmare for speed work over narrow, hard surfaces. If it goes down suddenly, it is just like a boiled pudding between the hard rim and the hard road. The sensation is frightening. I had it happen once, but I hope never again."

"Just my point," announced the Manufacturer. "You imagine the beginner experiencing the fright of a flat 28×3in. tyre on a solo mount! Why, it would frighten him off the make for at least a year, and in the meantime he would have purchased something else. Now"—the Manufacturer turned again to the Journalist—"what about skidding?"

Ideal in Certain Cases.

But the man of letters was not to be drawn. "I have stated," he said, "that the 28×3in. is ideal for rural pottering. The worse the roads, the more necessary it becomes, but I do not consider it suitable for blinding. It is dangerous. As for skidding—what one loses on the swings one gains on the roundabouts. The large tyre skids on smooth grease, but it bridges the ruts and tramlines. On the former, side-slip is generally the result of bad judgment; on the latter it is most to be feared. Therefore I do not consider side-slip as a point to be considered."

The Manufacturer knocked out his pipe. "From this the disadvantages are obvious," he said. "We have it that the 28×3in. is certainly desirable for Overseas tracks, but that it presents dangers that practically prohibit its general adoption over here. Now, proved that it has disadvantages, can you prove that it has advantages? Is there any appreciable difference between the machine fitted with 28in. wheels and the machine fitted with 26in.?"

"Yes," said the Journalist.

"If there is the same difference between the 28 and the 26 as there is between the 26 and the 24, I'm all for the 28," answered the D.R. "I am riding a lightweight for business purposes which is quite spoilt by 24in. wheels."

"Just about the same difference," announced the Journalist.

But the Manufacturer had one more shell to fire. "Your speedy T.T. mount would prove sluggish if fitted with 28×3in.," he announced. "If we adopted this size, I am half of the opinion that, though there would be a tremendous rush on it the first year, it would fall dead the second year."

Large Circumference Urged.

The Journalist waited for the lull, then he said: "Our conversation has centred round 28×3in., and what I wish to point out is that the objections raised are against the large, flabby tyre, not against the large wheel. There is obviously much to be gained by large wheels. They bridge the pot-holes, and tend generally to more comfortable riding. But the large tyre does not entirely fill the bill over here, so why not compromise by fitting 28in. wheels with 2½in. tyres?

"Speaking from practical experience, I consider the 28×2½in. tyre the best solution. It possesses the advantages of the large wheel without the disadvantages of the deep section tyre. Therefore I say the 28×3in. for Overseas, the 28×2½in. for the British Isles," and the Journalist sniffed loudly, which means, in Sioux parlance, "I have spoken."

Here we arrive at what fiction writers call a "dramatic crisis." This is where the Manufacturer should have shown up in an heroic light. It required much skill on his part to circumvent the Journalist's latter statement—so much skill, indeed, that he quietly gave it up, and so we must leave the reader to fill in his own happy ending.

A.C.U. ANNUAL REPORT.

FOR two years the activities of the Auto Cycle Union have been devoted to such national service as has been found possible and the protection of the interests of its members rather than to its main object in peace time—the encouragement of motor cycling. During last year 700 members took advantage of the concession by which they could, if on service, become honorary members. The fourteenth annual report, issued last week, goes on to state that there is evidence of increased activity among motor cycle organisations in our Overseas Dominions, and that after the war it is hoped that the A.C.U. may become more than ever both a national and imperial union of motor cycle organisations.

An Appeal.

The end of 1916 leaves the Union in a position to meet all liabilities out of liquid assets (that is to say, apart from stock or the reserve account) and still to have a balance in hand. But, in spite of that, the coming year is faced with a certain amount of misgiving. An earnest appeal is therefore addressed to all members to assist the Union by renewing their subscriptions promptly, and by obtaining new members amongst their motor cycling friends, and by recommending the Auto Cycle Union Insurance Policy.

The possibility of further taxation and other matters affecting motor cyclists, makes it imperative that the Union should remain financially and numerically the most important body solely representing motor cyclists in the United Kingdom.

"————?"

Suggestions for a Title.

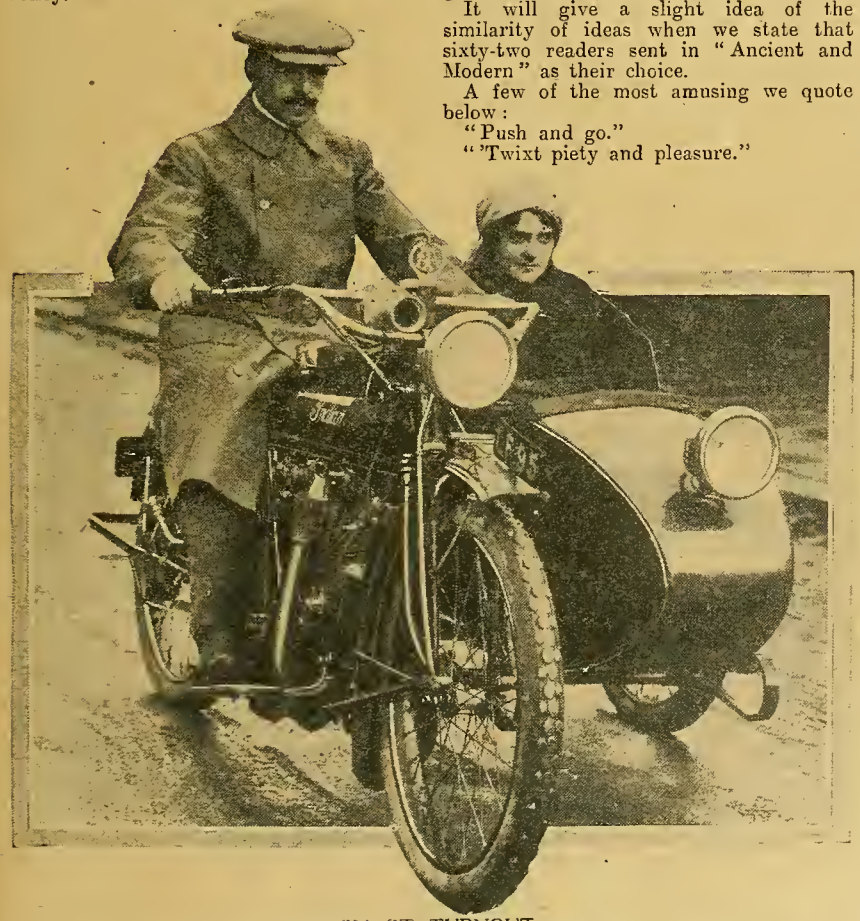
OUR simple invitation for an applicable title for a photograph brought hundreds of suggestions. We offered a copy of the new edition of "Motor Cycles and How to Manage Them" for the most suitable title, but deem three suggestions so deserving that we have sent a copy each to J. E. Newton, 62, Chapel Street, Penzance, whose title was "Petrol Committee views its handiwork" (owner has dropped dead on hearing "no more petrol"); G. W. Hester, 253, Mare Street, Hackney, N.E., "Gone to renew his licence, silly ass"; J. E. Thompson, 86, Watson Street, Hartlepool, Co. Durham, "C3 *versus* A1."

Several good titles were sent in practically identical in their wording. The petrol situation caused many to give vent to subtle innuendos concerning the Petrol Control Committee, which are generally good humoured, though sarcastic.

It will give a slight idea of the similarity of ideas when we state that sixty-two readers sent in "Ancient and Modern" as their choice.

A few of the most amusing we quote below:

"Push and go."
"'Twixt piety and pleasure."
"Eclipsed."
"Dourness and flexibility."
"Nothing doing."
"His perplexing rival."
"Kick-starters."
"Aspirations" (ass-spire-ations).
"What is it master likes so much" (apologies to Reid's stout)?
"Amity."
"A great thinker and a great doer."
"Wanting assistance."
"Balaam's new ass."
"Oh, what an ass I am."
"Foolproof."
"Alpha and Omega."
"Chacun tire de son cote" (Each pulls his own way).
"His master's v(o)ice."
"Everybody is using them but me—I'm an ass."
"Waiting and seeing."
"Pons asinorum. He *can't* get over it."
"Jack in wonderland."
"Two trusty sweaters."
"Brayhard and Bradbury."
"The other one has gone to pay his revenue."
"And who was your mother, Mr. Bradbury?"
"You're as fleet as any horse can be, and as dogged as a mule, but as stubborn as a donkey if your master is a fool." (The Kipling in embryo.)
"Ah! our spirits fail us."
"Tired and tyred."
"Riderless steeds."
"Anyway, I don't skid."
"Quietists: Waiting for the spirit to move them."



A SMART TURNOUT.

Mr. Ernest Ashford Bridgman (hitherto known by his stage name, Ernest Frasetti) with Miss Lottie Berend aboard a 7 h.p. Indian sidecar outfit. Mr. Bridgman is assistant manager of the London depot of the Hendee Manufacturing Co.

LECTURE ON AIR-SCREWS.

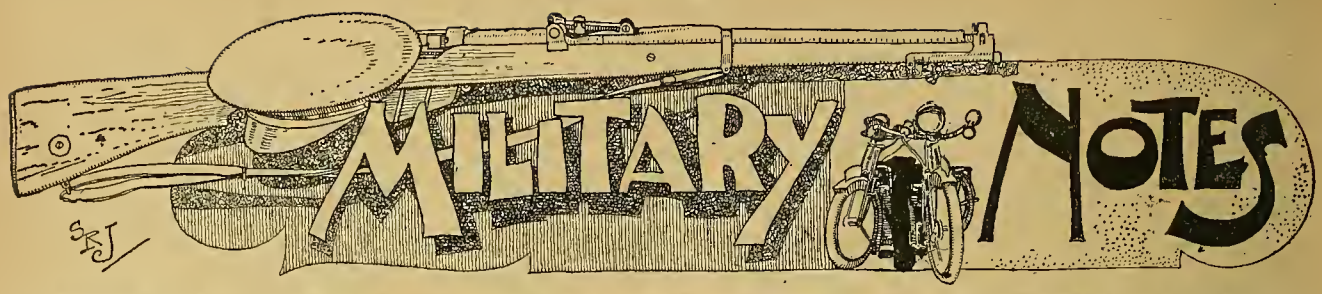
THE sixth general meeting of the session of the Institution of Automobile Engineers will be held in the Hall of the Royal Society of Arts, John Street, Adelphi, W.C., on Wednesday, March 14th, 1917, at 8 p.m., when Mr. J. Lawrence Hodgson, B.Bc., A.M.Inst.C.E., will read two papers on "Air Screws." Cards of admission are to be obtained at 28, Victoria Street, London, S.W.

Daimler Premium for Graduates.

An annual premium of £25 has been placed at the disposal of the Council of the Institution of Automobile Engineers by the Daimler Co., Ltd., and will be awarded to the graduate who submits the best paper on an appropriate subject in any session. This award is not intended primarily as a reward for original work, but rather as an encouragement to graduates to cultivate qualities that will be of practical use in their daily life.

THE REGISTRATION OF NAMES.

MR. ERNEST FRASETTI is well-known to all our readers as the assistant manager of the Hendee Manufacturing Co. (London Depot), and late of the music hall stage. The name Frasetti is his stage name, but as he became known under this name not only on the stage but as a trials rider, the name was retained. However, under the Registration of Business Names Act it now becomes necessary that he should be known by his legal name, which is Ernest Ashford Bridgman, and his friends are asked to note this fact.



FROM THE "GAZETTE."

TEMPORARY-LT. B. O. BARTON, formerly of the Spencer-Moulton Tyre Co., Ltd., and a member of the Public Schools M.C.C., has been promoted to the rank of temporary captain.

WOOLWICH MOTOR CYCLIST AS MOTOR BOATMAN.

FRANK WHITAKER, a member of the Woolwich and District Motor Club, has joined the Motor Boat Patrol. He is a well known rider and steersman of the Enfield first-aid fire outfit employed by Green Street Green, Kent, Volunteer Fire Brigade. Whitaker is now a chief motor mechanic.

Frank Whitaker, chief mechanic in the Motor Boat Patrol.

MOTOR DRIVERS IN THE INFANTRY.

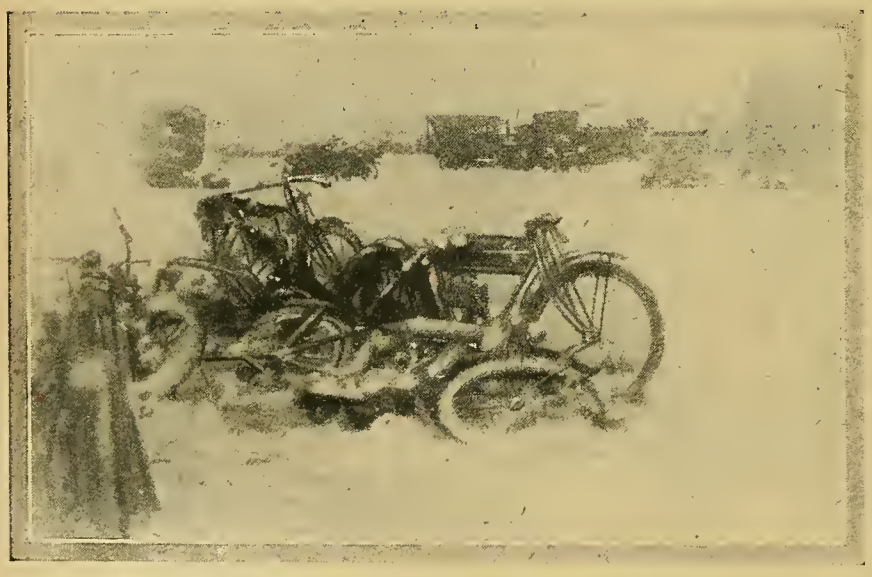
CONCERNING the leading article in our issue of February 22nd, on the subject of motor drivers of the A.S.C., M.T., recently transferred to the infantry, we are informed by some of the men affected that married men as well as single, and old recruits as well as new recruits, are included among the transfers. Their pay, it is added, has been cut down to infantry scale.

A MOTORIST'S PROMOTIONS.

CAPT. HERBERT BALE, A.S.C., M.T., the stalwart son of Mr. F. B. Bale, was last week gazetted a major, which promotion brings up the Swift Co.'s London Staff record to one major, two captains (one awarded the Military Cross), one lieutenant, and one D.C.M.

ROUGH USAGE FOR MILITARY MACHINES.

A GOOD many readers fondly imagine that they will some day be able to obtain a bargain in the shape of one of the motor cycles now being used by the military authorities. It seems to be the popular impression that the War Office will, ere long, release thousands for sale, that they will be disposed of by auction at absurdly low figures, and will constitute a real bargain, but we are, personally, not so sure of this. At any rate, to all who are saving up for this bargain *in embryo*, the photograph on this page will come as a shock, as it shows that even the best and latest designs of military machines are not kept under cover and looked after with the care that a private owner devotes to his machine. The picture incidentally explains the rapid deterioration in the appearance and value of a military mount. It is a pity that a motor cycle is not a suitable mount for the transport of a tarpaulin which could be used to protect the machine from the elements, particularly in rough wintry weather. Buildings or sheds to provide shelter for motor vehicles are not favoured in the zones of war.



NOT DERELICTS—BUT 1916 MILITARY MODELS.
War battered machines half buried in the recent snows.

HELMETS FOR NIGHT RIDING.

FROM G. W. Taplin, of the 22nd K.B.S., R.F.C., we have received the following interesting notes: "We have had some hard times during the recent cold weather, and until the woollen helmet was obtained it was almost impossible to ride a motor cycle for more than five minutes without stopping to warm one's ears, and if the English ladies would make them instead of mittens it would be a godsend to their soldier friends. They would be specially useful at night in the draughty hen roosts called billets.

G. W. Taplin, R.F.C. motor cyclist.

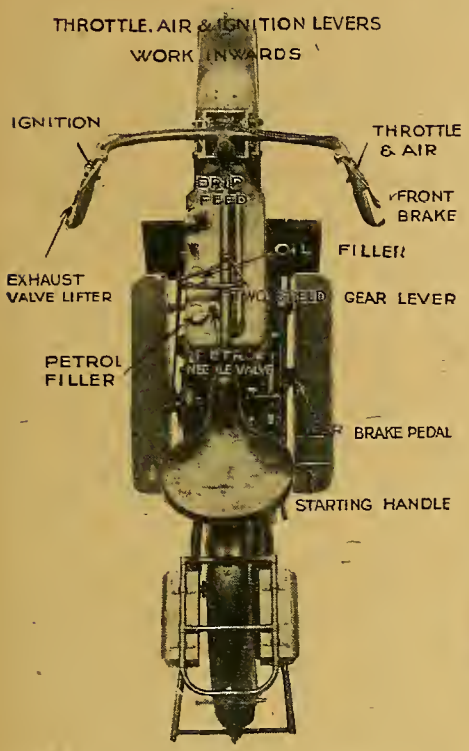
"The grumblers at the pot-holes in England ought to see the roads out here since the frost. They have turned completely over, and the chalk that is usually found a foot underneath has now climbed to the surface, and lies in big lumps, making it almost impossible to ride.

"The way the P. and M. sticks it is marvellous, and the tales I could tell you of what it has cheerfully done would make a good many other bicycles I could mention shake to pieces with fright, and get a Blighty touch the first journey.

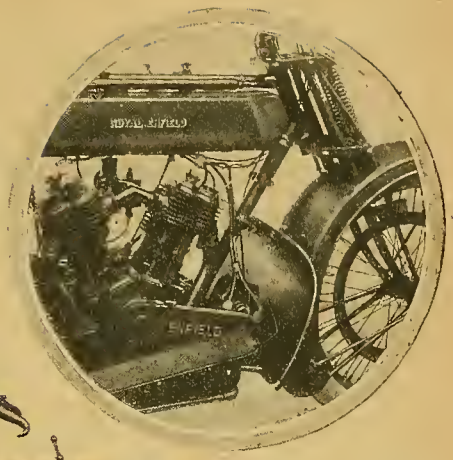
"The biggest surprise I have had is the Kempshall tyre; although only known to me by name in pre-war days, it has proved itself (out of the many varieties I have had issued) to be the best of the lot, some having given up the ghost in a day or two.

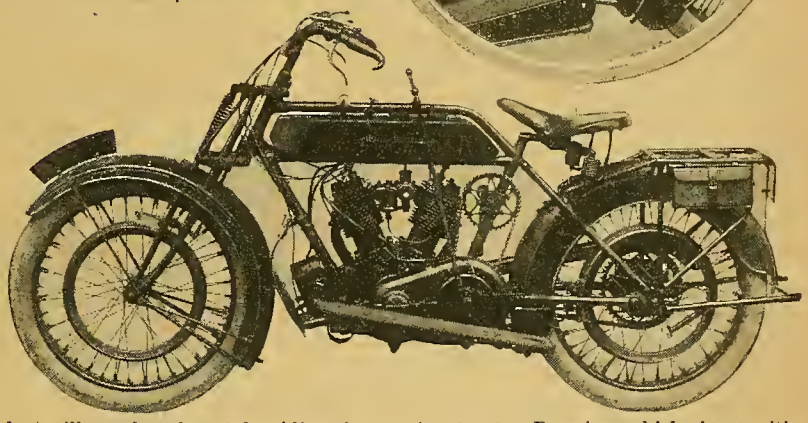
"I might add, in conclusion, that I look forward regularly to the arrival of *The Motor Cycle* and *The Light Car* each week, and after I have done with them there is a scramble for their possession by others in the camp. I must thank you for the two most interesting and instructive of motor journals."

THE ENFIELD RUSSIAN MILITARY MODEL.



The model illustrated is of 6 h.p., but 8 h.p. machines of similar design are being supplied for sidecar work. Special points of interest are: A ground clearance of 6in., semi-T.T. pattern handle-bars, the finish in service green, and a new magneto shield of liberal dimensions. The air throttle and ignition levers all work inwards, with their cables outside the handle-bars.





AMERICA'S USES FOR MOTOR CYCLISTS.

WE observe from *The Motor Cycle Illustrated*, of New York, that, in the face of an open break with Germany, with all its possibilities for trouble both from without and within the American borders, American military leaders addressed to motor cycle mounted guardsmen their first call for aid. The first Motor Battery of the 22nd Engineers was summoned together by motor cycle courier. Just two hours later, in detachments of ten men each, the one hundred expert motor cycle mounted soldiers were patrolling the whole of the New York City Aqueduct, with communication stations established at the big gatehouses along the line. Other work for American military motor cyclists was the mustering of the Motor Cycle Division of the First Field Artillery for despatch riding between Divisional Headquarters and other Commands located at various parts of New York City. We read that the incessant activity of these speedy motor cyclists throughout the day gave Upper Broadway its first taste of the things that are to come.

A group of motor machine gunners who joined the service through *The Motor Cycle*. All are now with the Heavy Section, M.G.C., and their names from left to right are: Gnrs. Dowse, Bullivant, Willis, and Belton.

MOTOR CYCLES FOR NEWSPAPER DELIVERY.

A MONTH ago a photograph of M. E. Taymans, late secretary Brussels M.C., and who is now a military motor cyclist attached to the Belgian Legation at Havre, appeared in these columns.

It is interesting to note that since the photograph appeared, M. Taymans's wife has taken up motor cycling for a living. She rides every day about thirty miles in two journeys on a 2½ h.p. F.N. motor bicycle fitted with a home-made sidecarrier, and sells the *Daily Mail* to the men of the Canadian Camp at Rouelles. We are told she can easily beat youngsters of about seventeen years of age on push bicycles.

This is another example of the infinite usefulness of the motor cycle.

Madame Taymans rides without any spares but a plug and a valve. She finds the little 2½ h.p. F.N. very reliable, but not quite as powerful as could be desired for the difficult road conditions. How Monsieur and Madame Taymans long for the trusty Premier which is awaiting them in Brussels! And, they add, any 3½ h.p. English three-speed mount would be a blessing. M. Taymans made the sidecarrier and painted it himself in his spare time. He has fitted a steel bar of about 25 lb. weight near the sidecarrier wheel to prevent the latter lifting too easily.

Madame Taymans, of Havre, and her 2½ h.p. F.N. sidecarrier.

THOSE QUIVERING PISTONS!

M. PAUL BIRAULT, Editor of the official organ of the French Army, says of the "Tanks": "I had the opportunity of seeing a Tank that had just been landed and whose mechanics were busy adjusting the motor. . . The inside is a perfect mechanical gem. One has only to look at the brightly polished steel and copper parts, the cylinders and quivering pistons, to see that the strength of the monster is throughout the work of intelligence."

Special Features

A WAR-TIME NECESSITY.

AVOIDING SKIDS.

"THE CRITICS" ON 26in. v. 28in. WHEELS.

"The Motor Cycle"—Twopence.

A fortnight hence the price of *The Motor Cycle* will be increased to twopence per copy (its original price) in order to maintain its present standard.

Rise in Price of Tyres.

Last week there was an increase in the cost of tyres. A pair of 650×65 mm. tyres complete of a leading make was advanced from 103/- to 117/-.

New Points in an Old Topic.

The interesting and important matter discussed by the Critics in this issue has many sides, and no doubt some of the points brought forward will open up new lines of enquiry in the minds of many of our readers.

A.C.U. General Meeting.

The annual general meeting of the Union, at which all members are entitled to be present, will be held at the Royal Automobile Club, Pall Mall, London, S.W., on March 29th, at 6 p.m. The only business to be transacted is the election of president and vice-presidents, and the reception of the annual report and balance sheet for 1916

Give a Definite Order.

In view of the further restrictions of paper, we advise readers who buy their copies of *The Motor Cycle* casually to place a definite order with their newsagent. There is sure to be still more difficulty in the coming months with respect to the supply of paper, and much disappointment would be avoided by the above simple procedure.

The Second-hand Market.

Our list of average prices indicates that the second-hand market remains pretty much awake in spite of petrol restrictions. This state of affairs is owing to the enormous number of machines used on national work of one kind and another, and there is no doubt that as time goes on the demand for cheap and rapid means of mechanical transport will remain steady

Analysis of a Substitute.

In view of the number of petrol substitutes now before the public, it will interest motor cyclists to know that a reader advises us that the analytical results of one of the substitutes offered to the motoring public show it to be a light petroleum lamp oil which can be bought at about half the price at an oil shop.

A Route to Avoid.

A correspondent who signs himself "LL 9695" writes us as follows: "The main road between Reading and Basingstoke is at the present time dangerous to motor cyclists, the worst part being near Swallowfield, about five miles from the former place. Two days ago I was nearly pulled up three times in a short distance by my footboards fouling the road, but luckily the sidecar saved a spill. Motorists desiring to go from Reading to Basingstoke should turn to the right just short of Three Mile Cross—three miles from Reading—going through Beech Hill, where there is a very sharp down hill left-hand turn round a public-house, and rejoining the main road at the Wellington Arms"

On Sunday last the Mayor of Coventry (Mr. Alick S. Hill) reviewed the Motor Section of the Coventry Special Constabulary. The Mayor, wearing his gold chain of office, was accompanied by the Chief Constable of the city (Mr. C. C. Charsley).

Substitutes—of the Oily Kind.

Last summer there were a score of petrol substitutes before the public. Our present list includes thirty-four names—some of them weird and wonderful.

The National War Funds.

At the week-end the principal war funds stood as follow:

The Prince of Wales's Fund (distributed £3,539,719)	£6,039,423	0	0
British Red Cross Fund	6,223,426	0	0
Tobacco Fund	126,206	0	0

Extension of Manufacturing Permit.

Manufacturers of motor cycles not engaged on Government work have had their permits to manufacture extended, but new machines may only be placed in the hands of those on work of real importance, such as doctors, farmers, etc. The importance of Overseas exports to assist our exchange is emphasised in the letter conveying the decision.

Agents to obtain Permits.

Agents in future must obtain permits to dispose of new motor cycles (and presumably cars). Formerly a manufacturer had to obtain a permit, but now a certain number of machines may be supplied to agents, and the latter must give an undertaking that they will not be sold without a permit from the Director General of Mechanical Transport.

An Amusing Suggestion.

America's latest suggestion to check excessive speed of motorists is that the vehicle should have a State-sealed box or receptacle in which should be placed cards bearing the name of the owner of the car, and his photograph and address. It is to be made so that by an ingenious automatic arrangement one of these cards should be liberated and fall on the road if a certain fixed speed were exceeded, the prosecution of the owner thus being an easy matter.

Germany Traded on our Ignorance.

In his paper, "The Magneto: Its Function, Design, and Construction," read before the Coventry Engineering Society, Mr. E. A. Watson, M.Sc., brought forward a point which illustrates how we were exploited by the German magneto manufacturer before 1914. The German policy was to recommend various sizes of magnetos for different sizes of engines—a large magneto for a large engine and a small one for a small engine. Mr. Watson was convinced that this is entirely unnecessary, and was merely a little device on the part of the Germans to profit by our ignorance, for, believing the tale, we were content to pay considerably higher prices for large magnetos.

An Early Proof.

Our sister journal *The Autocar* points out that one of the first men to explode this theory, though he had few backers, was Mr. C. R. Garrard, as at that time (eight or nine years ago) the Clement-Garrard cars were carrying everything before them in competition circles, and it was a matter of general comment and wonder that the cars were fitted with such small magnetos.

"The great point of this contention is," points out *The Autocar*, "that one size of magneto is practically suitable for any size of engine," which, of course, means much cheaper production.

Help to Conserve Supplies of Paper.

To prevent waste of paper, we would once again urge readers to order *The Motor Cycle* from a newsagent, and not purchase their copies anywhere. From the 22nd inst. the price will be 2d.

Not Hot Air, but Gas!

We are informed that somewhere in U.S.A. "Speed Cop" E. L. Heels took his 1917 Henderson, put in one gallon of gas, and rode 104½ miles. Was it acetylene gas? If so, according to the opinions of some of our readers, he might have travelled still farther.

Rudge Workers Entertain the Wounded.

On Saturday last a team of Rudge sidecars conveyed fifty-seven wounded soldiers from the Coventry and Warwickshire and Courtauld's Hospitals to the Rudge Works. A tea and entertainment had been provided by the girls working in the aeroplane factory, and the enjoyable time was thoroughly appreciated by the wounded men.

Petrol v. Substitute.

Substitutes are all the talk just now. Some riders would drop them to-morrow for ever if they could get petrol; other motor cyclists can be heard vowing that they will never pay a high price for petrol again, now that satisfactory substitutes at a reasonable figure are obtainable. It is largely a case of carburetter and the system of vaporising adopted, as we have shown by recent articles in *The Motor Cycle*.

Use of Petrol.

Enquiries continue to reach us concerning the matter of petrol permits and the use of petrol. If, therefore, readers will kindly note the following, it will save a great deal of correspondence:

A stock of petrol, on which duty has been paid, can be used after March 31st or at any time.

A petrol permit can be used after March 31st until it is exhausted.

Full duty petrol permits are not now being issued.

A small stock of petrol on which duty has been paid can be transferred to a friend without entry on his ticket.

There are to be no restrictions as regards the use of motor vehicles after March 31st.

A Temporary Membership Scheme.

The Finsbury Park Cycling and Motor Cycling Club has adopted a scheme whereby, for a nominal subscription of 2s. 6d. per annum, members of other clubs which have ceased active operations may become temporary members, entitling them to the same benefits as ordinary membership, except the power to vote at club meetings. Such membership will automatically terminate on December 31st of the year in which peace is declared.

Women Drivers Wanted.

Women motor drivers are urgently required by the Director General of the Mechanical Warfare Supply Branch of the Ministry of Munitions. The work will be in Leicester, and will consist of driving 2-3 ton motor lorries. There are certain physical specifications laid down regarding weight, height, and constitution. Applications for these positions should be made to the Chief Stores Officer, Ministry of Munitions, M.W.S. Stores, Grafton Place, Leicester.

Simple Arithmetic.

Few motor cyclists realise the marvellous rapidity with which the cycle of operations in a high speed engine are performed. An article, entitled "Some Simple Arithmetic," in Wednesday's issue of *The Light Car*, shows that in a four-cylinder engine revolving at 3,000 r.p.m. a magneto has to deliver 100 sparks a second. A twin two-stroke requires the same number of sparks at the same speed. The article gives other figures equally interesting and astonishing concerning crankshaft and piston speeds.

The French Way.

Both in peace time and war time the French are far more logical in their method of taxing road users than we are in this country. They realise that motorists are not the only people who benefit by improvements to the roads. In consequence, horse-drawn vehicles are made to pay their share in the upkeep of the highways, as privately owned carriages do in this country. To observe the damage done by horse-drawn lorries and farm vehicles during this last week, now that the roads are soft through being lifted by the frost, is proof enough that a more equitable system of taxation should be devised.

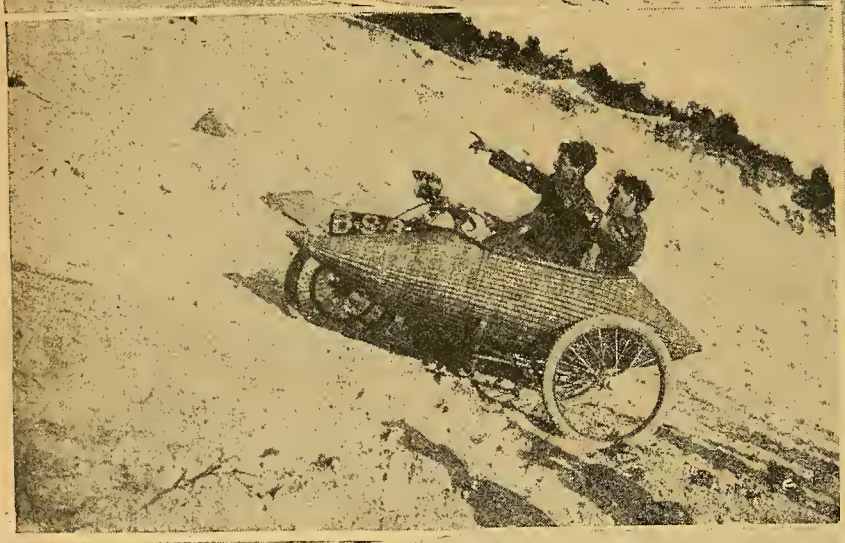
REBATE ON LICENCE FEES.

The Recommendation of "The Motor Cycle" Adopted

ON February 15th we discussed the question of the cessation of petrol licences, and strongly objected that the decision should have come immediately after the end of January, during which month licences had to be paid on motor vehicles. We asked, "Do the authorities imagine that motor cyclists are willing to pay a full year's licence for a quarter of a year's riding?" We further pointed out that the Government could not in justice retain in full the fees which had been paid this year. The attention of the A.C.U. was drawn to the matter. Many letters of support reached us from readers, and all such will be particularly interested in Mr. Bonar Law's announcement in Parliament on Monday last, the 5th inst., which is given hereunder:

> THE CHANCELLOR OF THE EXCHEQUER, replying to Mr. Doris (Mayo, W., Nat.), said he had decided to introduce a clause in the Finance Bill providing that where the owner of a private car is unable to use it owing to the restriction of the supply of motor spirit he shall, if he surrenders his motor car licence before June 30th, be entitled to repayment of one-half of the duty which he paid on taking it up. (Hear, hear.)

A motor cycle is a motor car within the meaning of the Act.



ASCENT OF MOUNT CLARENCE.

FIRED by the example of two drivers of a Overland car which had succeeded reaching the summit of Mt. Clarenc Western Australia, T. J. W. Evans le Perth on a 3½ h.p. B.S.A. with O. S. Burt in the sidecar at 6 a.m. on September 16th f Albany. The roads at first were very bad, a the riders were much troubled by "spoo drains and patches of loose gravel and san In spite of these difficulties they reach Kojonup about half an hour earlier than th expected. But owing to belt trouble, and t slow driving necessary when it became dar Albany was not reached till midnight.

On the following day a successful attempt w made to climb Mt. Clarence in the presence a large number of Albany residents, and t zigzag course recently traversed by the Ov land car was chosen. There was no road, a the riders had to pick their way as they b could over the boulders, sand, and round sha turns. (In some cases the bicycle and sidec

MANUFACTURING PERMITS EXTENDED.

New Machines for National Work Only. Agents in future to obtain Permits to supply New Motor Cycles.

IN one of our leading articles this week we review an important letter issued by the Ministry of Munitions (Department of the Director General of Mechanical Transport) concerning permits for the manufacture of new motor cycles and their distribution. Henceforward, agents will require to obtain permits to supply new machines. In our leader we commend the Director General of M.T. for his clear and concise statement, and as further proof of the fact that a business man has dealt with this subject we may cite the fact that a copy of the letter issued to manufacturers, together with a covering note acquainting us with the position, was sent to the Editor of *The Motor Cycle*.

The letter is given *in extenso* hereunder, since the new ruling affects the buying public to a considerable extent :

"Ministry of Munitions of War.

"Dear Sirs,—In regard to the Permit which has already been granted you to continue the manufacture and assembling of motor cycles, I am now directed to inform you that the whole question has been receiving the most careful consideration of the Ministry, and it is hoped that it may be found possible to place orders with you for work in connection with some Government Departments, though at the moment no such promise can be made definitely

"I am, therefore, to inform you that the Permit already granted you is hereby extended until such time as you receive such orders, when it is to be understood that you will immediately give up work under this Permit and concentrate your whole energies upon the Government order.

"Under this Permit it will be necessary for you to apply to this Department before effecting the sale of any motor cycles made by you, but in order that all firms may be placed upon the same basis, this condition will only apply to machines completed by you after February 24th. I may say that, in view of the great demand it would make upon the time of our inspectors, it is not proposed to take any steps to check the stock of cycles already made by you, and not, therefore, subject to the above condition, but it is to be left to your honour strictly to abide by the spirit of this letter, and to schedule all machines now complete and keep them separate from those completed after February 24th.

"I cannot, however, too strongly urge upon you the absolute necessity in the national interest of exercising the greatest possible care in the sale of all these machines, so that they may only be placed in the hands of those who must have them for work of real importance, such as doctors, farmers, etc. As a guide, may I say, for instance, that it is not always in the national interests that a motor cycle should be used to enable a man to get to and from his work; in some cases he could live nearer his work, while there are, of course, cases where the housing problem is so difficult that he could not be asked to do so.

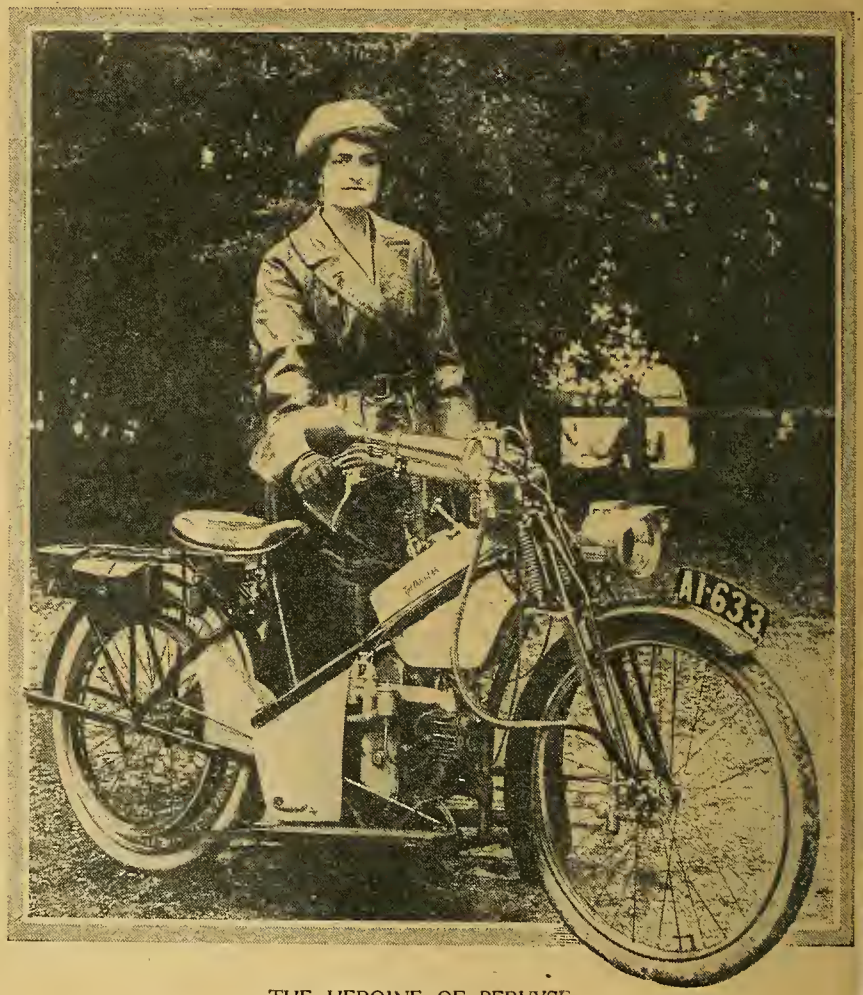
"The difficulty, however, could be overcome to a very large extent by your exercising your utmost endeavours to export the whole of the motor cycles manufactured by you; this would not only save a certain amount of petrol consumption in this country, but would also benefit the exchange.

"Under the terms of this letter there will be no objection to your selling a certain number of machines to your agents, provided that you are thoroughly satisfied as to their *bonâ-fides*, and that they will give you an undertaking that they will not dispose of the machines without a Permit from this Department. No machines should, however, be sold to agents in whom you have not complete confidence that they will loyally carry out the terms of this undertaking.

"I shall be glad to hear that you are prepared to accept the conditions imposed and implied in this letter, and to give you any further information that I can.

"I am, yours faithfully, BASIL H. JOY,

"For Director General Mechanical Transport."



THE HEROINE OF PERVYSE.

Baroness de Serclaes, the heroic Englishwoman who, with Miss Marie Chisholm, was decorated by King Albert for her bravery in the great retreat. These ladies are now Chevaliers, and entitled to military salute. For months they lived in a cellar at Pervyse, where they did marvellous first aid work in trenches. Baroness de Serclaes is a keen motor cyclist, her mount being a lady's model Douglas.

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

MOTOR-ASSISTED BICYCLES.

Sir,—I see in your issue of March 1st that "Cyclist" expresses the hope that inventors will provide for the declining strength of veteran riders. I think I may lay claim to be a veteran at seventy-three years, and am well provided for with a 2½ h.p. four-stroke. I am 12½ stone, and yet it takes me up any ordinary hill. It has neither pedals nor speed gear, and has covered over 6,000 miles without any trouble whatever. If "Cyclist" knew the comfort and convenience of a machine of that sort, he would never think of pottering about with a motor-assisted bicycle nor blame the inventor for not providing one for him.

Insch. ONE OF THE BOYS.

YEAR OF ORIGIN.

Sir,—Two friends of mine in this district (Wallasey) and I each bought a second-hand 3½ h.p. Triumph. When comparing purchases we endeavoured to ascertain the year of origin of each machine, but were unable to do so definitely. I therefore wrote to the Triumph Co., Coventry, quoting the engine numbers, but the answer I got was "that it was not their custom to give any information regarding their machines, except to the original purchasers." Now that person (whoever he was) would not need to ask such a question, because he would know when he bought it, but if we should try to sell our machines, how can we give the date of origin when, as owners of machines, we are treated (as I consider) so unfairly? W. R. WEAVER.

PORT DESIGN IN TWO-STROKE ENGINES.

Sir,—I shall be pleased to have a friendly test with "Metro." However, why waste precious juice running out to Sunrising, when we have Weatheroak Hill so near home, which would be quite as good a test for both machines? I will let him know when I am fit; at present I am in the doctor's hands.

Our friend "Ixion" seems to doubt my statement *re* my Excelsior's hill-climbing. What about the following done on a Baby Levis? I climbed Fish Hill, Broadway, on this machine after twelve months' hard wear; also toured the Wye Valley, Hereford, Ross, Symonds Yat, Monmouth, and home *via* Gloucester and Evesham, climbing all hills with ease. I should like to hear other two-stroke riders' experiences as regards hill-climbing, etc., as according to "Ixion" and "Metro" my Villiers is no ordinary engine.

Birmingham. EXCELSIOR.

REAR SPRINGING OF MOTOR CYCLES.

Sir,—I read with interest an article on the double eccentric spring hub, and beg to offer a few comments. (1.) I agree that there is a question as to how much movement to give to the wheel, but I think 2in. total rise and fall would be sufficient to damp out only small vibrations, and anything in the way of a pot-hole or tram "stud" would be felt very badly, at least this is my personal experience. The ideal would be to have, say, 2in. movement against moderate resistance, after that rapidly increase the resistance up to, say, 3½in. This, I believe, has already been adopted by at least one designer with great success. (2.) With regard to the twisting action of most spring frames due to deletion of triangle A.D.B., this is a point which is not generally understood, and is most important. It has been overcome by joining the points at each side of E to the top of the carrier where the spring is fastened, as on the "A.B.C." But this puts great strain on the bearing E; in fact, all side strains. I do not quite see why the axle I is the keystone of the whole structure, but surely it is never missing? One hopes not when going downhill! (3.) I can understand how this ingenious hub works on the rear wheel, but fail to see why it should be adopted for the front. Where is the radius rod, and if there, why? C. W. PIDCOCK.

[The axle is always present but it does not always rigidly connect the ends of the stays.—ED.]

A STURDY MIDGET.

Sir,—I notice in "Ixion's" "Comments" in your last issue that a country agent has pointed out that the modern baby engine cannot approach the performance of the ten-year-old 2¾ h.p. single-cylinder o.h.v. J.A.P.

If the country agent mentioned will refer to the present British motor cycle class records he will see that the modern single-cylinder engine more than holds its own with the ten-year-old one.

I refer to the records in Class B (350 c.c., 2¾ h.p.) as under:

	Date.	Machine.	M.P.H.
Five miles ...	14/ 6/13	(one-cyl. Singer) ...	64.93
Ten miles ...	9/ 8/13	,, ,, ...	60.56
Fifty miles ...	16/ 6/13	,, ,, ...	63.88
One hour ...	19/10/13	,, ,, ...	62.68

All held by G. E. Stanley.

Then again, in the Miniature Class A (250 c.c. 1½ h.p.):

	Date.	Machine.	M.P.H.
Kilo	17/4/14	(one-cyl. Singer) ...	57.65
Mile	17/4/14	,, ,, ...	58.63
Five miles ...	25/7/14	,, ,, ...	52.29
Ten miles ...	25/7/14	,, ,, ...	51.28

All held by W. A. Jacobs.

I consider that the mile record, as above, is of particular interest, and, when peace comes, it will be interesting to see who is going to knock off the necessary 1⅘s. to bring this speed up to 60 m.p.h. G. J. McINTOSH.

THE FLAT TWIN AT THE BAR.

Sir,—We have read with the greatest interest the discussion which has been going on for some time between Mr. Bradshaw and Mr. O. de Lissa on the merits of the flat twin and V engines. No wonder that the discussion got sometimes rather hot considering the spirit of the fighters.

As manufacturers of the M.A.G. engines, we have naturally the highest interest in seeing these defended against any newcomer, but at the same time, we did not see our way to taking part ourselves in the discussion, as we never know what type of engine we may elect to build in the future. For the present, we are satisfied with the results we are obtaining with the V type, although we highly appreciate the performances of the small flat twin engines, of which, however, we have no personal experience. As to the powerful flat twin, we believe it will be better to keep the discussion open until actual results will have provided the necessary facts.

We would thank you for informing your readers that we are entirely unconnected with this controversy, and that principally and systematically we have always avoided and will always avoid all kinds of polemics, technical or personal.

If we venture at this issue to break our silence it is because we have seen with extreme regret that in *The Motor Cycle* of February 1st, "A.M.I.E.E." extends the discussion to a political one with a vicious hit against the Swiss industry in general.

We congratulate Mr. Little John and Mr. de Lissa on their replies to "A.M.I.E.E." in the following issues of February 8th and 15th, and beg to add that probably a much

larger portion of the Swiss industry would devote its entire energy to work for the Allied requirements if it could be supplied with the necessary materials. If up to the present the Swiss industry has been able to render services of the very highest importance to the Allied Armies, these efforts become more difficult every day, as material gets scarcer and harder to obtain.

As to the fairy-tale of the 300 submarine engines, this has been denied again and again, and we believe it superfluous to add a further denial to those already made with better authority than ours. THE MAG ENGINE CO.

Geneva.

CONCESSIONS TO SERVICE MEN.

Sir,—Your suggestion of concessions to Service men is one that deserves every support. Last year it cost me 25s. tax for less than 300 miles, and I was fortunate enough to have three or four seven-day passes. Part of the time was occupied in overhauling and cleaning up—one of the things for which you suggest an alternative. This year I have paid the £1 tax, and have petrol at home for a couple of hundred miles; but all our passes are stopped for the present, and I hardly seem likely to be able to use the machine until after the war.

I am pleased that *The Motor Cycle* fully maintains its old quality and quantity, and keeps up-to-date and interesting. I could not do without it.

With regard to the discussion as to who should hold driving licences, I have had to wear glasses since I was about fourteen, and have now been motoring for about five years, yet my licence is clean, though I seldom keep within the limit when out of town. It is proper driving that counts, not good ears and eyesight. (Rfn.) F. A. BUNN.

WHO SHOULD HOLD DRIVING LICENCES?

Sir,—It is a common trick for those who have not facts or figures on their side in an argument to try and be "funny" (?) I cannot congratulate your correspondent in his attempts in this direction in last week's issue of *The Motor Cycle*. His statement that I should fail to pass the test of "general intelligence" is, unfortunately, an infringement of a patent, as a previous correspondent made the same brilliant remark in your paper of February 15th!

With regard to his query about deaf riders riding in the middle of the road, my experience is that in the country lanes *all* riders take the middle of the road. This is, of course, quite safe so long as the rider has good sight and hearing; but, if not, there is good chance of an inquest. Endorsement of licences has nothing whatever to do with the question, except in the case of *town* riding. In the country there is seldom any policeman about to witness an accident, hence conflicting evidence and no endorsement of licence.

It is certainly rough on a disabled soldier if he is refused a licence, but what about the general public if he be granted one and through defective sight or hearing causes a smash up (as has often happened)?

The best vindication of the truth of my statements is to be found in the long list of motor accidents which occur every year. Motoring is really one of the safest of sports *if only* a little intelligence is used in driving. Most drivers, if they have travelled over a certain road two or three times without meeting anything, seem to think that there is no need to use their horns the fourth time, and trust to luck. In the winding lanes I meet such almost every time I am out, and if *I* did not use my horn there would be a daily smash up, as lanes are not wide enough for two to pass in many places. M. HITCHCOCK.

Sir,—In your issue of the 15th inst. appears a letter from a Mr. A. L. Gray, who, in advocating that persons unfortunately minus the sight of one eye should be debarred from holding driving licences, states that in the only collision in which he has been involved the "other party" was afflicted in this manner He further states that, owing to his disability, the "other party" was unable to judge the distance between his and Mr. Gray's motor.

He then applies this—his opinion—to all one-eyed motorists.

How are we to judge if Mr. Gray was in any degree culpable in this collision, and what evidence can he produce to show that such is not actually the case? It is not unreasonable to suppose that your correspondent may be a road hog of the worst type; on the other hand, he may not. The bad taste of his second sentence is a portent favouring the former supposition.

Mr. Gray's letter gives no clue as to whether or not he has had any military experience. My own extends over thirty months, and during this time I have learned to respect the distance judging abilities—in visual range taking practice and in the field—of those members of the Forces who in the execution of their duty have lost one eye.

It is men such as these that Mr. Gray would deprive of the pleasures of motoring on the King's highway, simply because he, being blessed with two eyes, "is able to see what they cannot." At least so he tells us. C.Q.M.S.

Blyth.

[Many other correspondents adopt this point of view.—Ed.]

Sir,—Your correspondent, Mr. M. Hitchcock, is evidently not a motor cyclist or he would not talk as he does. I submit that there is not any reason why partially deaf or deaf persons should be precluded from holding a licence if they—

(1.) Keep to the left.
(2.) Use their eyes.
(3.) Carry a reflector on their handle-bars.
(4.) Use care and observe the rules of the road when passing from main roads to byroads or *vice versa*.
(5.) Use a hooter whether they can hear it or not.

As to runaway horses, so few of these creatures are met nowadays that motor cyclists have little to fear from them.

I suppose in a fog a continuous sounding hooter is to be used. Imagine the result in a crowded, trafficky area. If £5 is to be levied every time the motor cyclist fails to use his hooter when he cannot see fifty yeards before him, a host of policemen will be required to watch all such places, or perhaps Mr. Hitchcock will suggest a scheme.

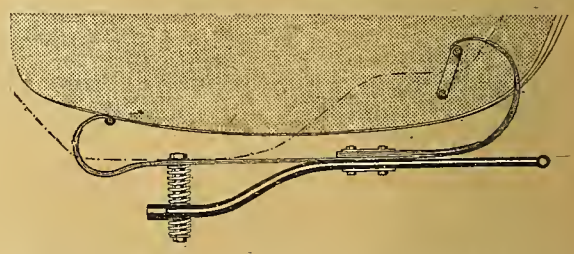
As to "general intelligence" test, what are standards of "general intelligence" required?

Also does he include in his bann those maimed partially, and to whom he would deny the pleasure of riding a motor cycle with specially arranged controls? L.H.T.

Ashby-de-la-Zouch.

FITTING A NEW SIDECAR BODY.

Sir,—Seeing one or two notes published recently of readers making improvements to their machines to bring them up-to-date, I send this as a good tip to make a 1913 Enfield look modern. You will know that the sidecar chassis has the



front dropped and the sidecar is of the chair pattern, which I got to dislike, as the sidecar is the first thing to make a combination look out-of-date. I did not fancy paying the price of a complete new one, so I bought a new body and fixed it in the following way: I made a pair of shackles 5½in. long for the existing back C springs, which I moved backwards as far as possible (2½in.) and fastened with bolts. I got from a local garage a pair of front C springs. These had been of the back and front all in one variety. The back being broken, I got them cheap. I then assembled the front spiral springs, which formed a spring platform for the flat springs. A bar under the front finishes the job, which looks well and rides well. BOB BRIERLEY.

FORCED INDUCTION FOR FLAT TWINS.

Sir,—As "C.L.V.C. 2872" in his letter in your issue of February 22nd has asked for a criticism, I, as a designer, would like to say a few words. I will answer his article, for the sake of space, in the order of his lettering. *(a.)* This would be even worse than employing long induction pipes, which, after all, can easily be lagged or bound with asbestos. *(b.)* Granted *(c.)* In the first place, he has not told us if the cycle of the pistons is in opposed direction. Secondly, how on earth does he get twice the c.c. of one cylinder compressed into the crank case, by what means, and also how does he get this volume forced

into one cylinder? Does "C.L.V.C. 2872" know that if the former principle were possible, the extremely high compression would be likely to cause pre-ignition? *(d.)* This is only complicating the mechanism. The employment of two valves for exhaust is common in the speed world.

To sum up, the use of automatic piston inlet valves should be avoided at all costs. They are horribly inefficient, likely to gum up, dangerous, difficult to get at, and impossible to fit in a motor of small c.c. In fact, no design has yet been made to make the piston valve a real success. I should be interested to know, therefore, why a motor of 2¾ h.p. on this principle should develop more power than the present 3½ h.p.

I shall be glad to answer any questions that "C.L.V.C. 2872" may put to me. W. F. MAITLAND EDWARDS.
B.E.F., France.

COMMENTS ON THE POST-WAR MATCHLESS.

Sir,—Everyone during the past few weeks has been gazing with interest at the new Matchless which is going to be placed on the market *après la guerre*. But there is one point in particular I should like to draw Messrs. Colliers' attention to. Their announcement in a recent issue drew attention to the detachable wheels with knockout axles. So far I do not complain; the wheel is quite easily detachable. But unless the mudguard is movable the wheel cannot be taken out without lifting the machine up, so that it needs two people to change a wheel. I should suggest that the present type of rear stand required redesigning, so that it would lift the machine considerably higher and give more clearance to get a wheel out. If the "stand" were made so that it "jacked" the whole back of the machine and sidecar up by means of a hinged affair on the back axle of the outfit between the two wheels, this would help considerably, and with such a heavy machine a stand such as the Pope machines were fitted with would be an improvement.

As to the abilities of the machine I await the peaceful days to see what it can do. I will admit being interested, even though it is a horizontal twin, and since it is made by Messrs. Colliers it should be good; and I have no doubt they will find their present machinery very useful in turning the engines out in large quantities. LITTLE JOHN.
S. Farnborough, Hants.

SINGLE V. TWIN-CYLINDER ENGINES.

Sir,—Concerning singles and the letter from "Progress," gear ratios are chosen apparently to make use of the high-power-at-low-revolutions characteristic. There is usually a big gap between the top and the middle gears. On a gradient just too steep for top there is great temptation to allow slow tugging, because the results of a change down to middle gear are: gear box noise, racing engine requiring continual attention from throttle, and a big drop of road speed, which makes it almost impossible to change up again without knocking until the road is level or nearly so, owing to the fact that the engine has become hotter with decreased wind on middle gear. This shows the need for a four-speed gear box, as a low emergency bottom gear must be retained, but if possible *the two higher gears should both be direct.*

The four-stroke single as a type requires a greater number of gear ratios than twins, four-cylinders, and two-strokes. It also requires greater flywheel effect, and this fact is seldom appreciated. A large diameter outside flywheel of heavy rim, combined with a kick starter of longer leverage, would make starting up independent of temperature and amount of oil in crank case. The latter could be of cast iron for cheapness, as its size would be small and ground clearance large. W. R. DEUCHAR.

Sir,—I was very interested indeed with "Ixion's" remarks about the 7-9 h.p. solo machine, being a rider of this particular type of machine for over two years.

He states he dislikes the weight of these machines, and I wonder if he has ever tried the Indian road racer, as this machine is no heavier than the majority of the latest singles, and the balance is perfect.

I consider, myself, this machine to be the finest solo motor cycle on the road, as it can be throttled down on a high gear, will tick over in free, and show remarkable acceleration, and is speedy enough to satisfy any speed merchant.

I have no intention of ever going back to a single, and shall stick to the 7-9 h.p. twin, unless the flat twins are proved to be better in every way.

The only drawback to the Indian road racer is that no kick starter is fitted, and one has to push to start.

Usual disclaimer, please. CUT ALONG.
Hampstead, N.W.

Sir,—I should be pleased if you could find space in your interesting paper, of which I have been a reader for just over seven years, for the following remarks.

I read in *The Motor Cycle* a few weeks ago some remarks by "Ixion" and "Road Rider" on the single and flat twin controversy. I must say that I agree with "Ixion" on the matter. I have had a little experience on singles, and some of the best makes—in fact, I own a single; but I fail to see where a 3½ h.p. single can be compared with a 3½ h.p. flat twin, especially if the flat twin has a spring frame. I live near a friend of mine who has in his garage two flat twins, both of different makes. Last week I had the pleasure of sampling one of these mounts for the first time. I must say that this was the most comfortable machine I have ever ridden. The springing was far superior to that of any single I have ridden yet, and the acceleration was more like that of a car.

"Road Rider" remarks that the single is far more accessible than the flat twin. But before the flat twin has been on the market as many years as the single it will be quite as accessible. GREENHORN.
Bodmin.

Sir,—Having had some years' experience with internal combustion engines of all types, and being an aero engine designer, I should like to express an opinion with regard to the matter. For the sake of space I will try to be brief.

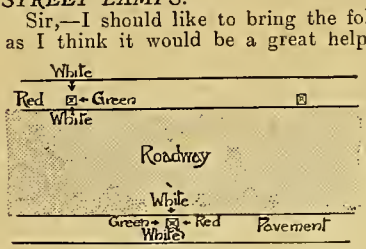
From an engineer's point of view there is no comparison between the two. I have nothing to say against the single, as it has been brought to a stage of almost perfection; but the multi-cylinder, if well designed, is much better, not only in theory, but in practice. A point in brief. In a single four-stoke all explosive energy is concentrated on one stroke; the other three movements are, necessarily, waste. There is enormous stress on that single movement, which in a twin is broken up into two, each cylinder receiving its share, therefore eliminating to a great extent the shock imposed for that power upon the moving parts and bearings. The twin again lends itself to more perfect balance than the single, and perfect balance is the keystone of engine design.

With the flat twin we have the nearest approach to the perfect motor cycle engine. The balance is perfect, the explosion stresses being opposed, as the two engines fire after each other, besides a hundred and one minor details of design. I am glad to see that Mr. Collier, who has done such a lot for the motor cycling world, has at last gone in for the flat twin.

To finish, a man with a fair knowledge of petrol motors need have no trouble with the modern twin. I am afraid most arguments to the contrary have been made or based upon machines of rather inferior design. The flat twin has only just lately been properly recognised, and I am certain that that type of machine will ultimately be adopted.
O. F. MAITLAND EDWARDS.

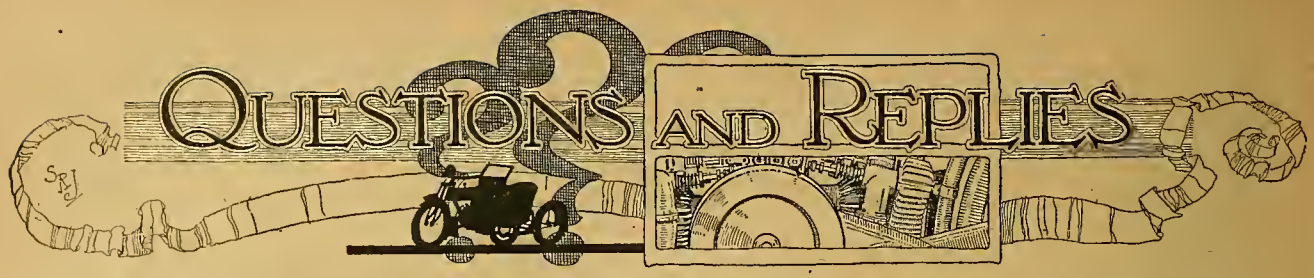
STREET LAMPS.

Sir,—I should like to bring the following idea before you, as I think it would be a great help to all motorists.



A suggested scheme of multi-coloured street lamps. The sketch illustrates our correspondent's ideas.

Very often when driving at night you notice a lamp-post come into view, and, owing to a bend in the road, it is impossible to tell which side of the road the lamp is on. Now if the lamps were painted in the following manner, I think it would save a lot of accidents and be a great benefit to all drivers, for it would only be necessary to keep a green light on the right and a red on the left. Of course, a central lamp at a corner would be green on all sides. CHARLES ROOTE.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C., and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

A Question of Altitude.

Which is the highest point above sea level in the county of Somerset?—F.E.R.

The highest point above sea level in Somerset is Dunkery Beacon, on Exmoor, West Somerset, the altitude being 1,707 feet.

Vibration.

(1.) I have a lightweight motor bicycle, out of which I cannot get more than 25 m.p.h., and at that speed the vibration is very excessive. (2.) After I have opened the throttle halfway, it makes no difference to the speed. The engine has been cleaned.—T.G.C.

(1.) The trouble is probably due to the engine being badly balanced, unless you mean road vibration which can be modified by fitting a more comfortable saddle. (2.) Possibly too large a jet has been fitted, and the engine chokes owing to too much petrol, or it may be that the area of the inlet pipe is equivalent only to half throttle.

Excessive Noise.

I bought a 1915 motor cycle new in October, 1916. This is the third mount I have had, and the noise it makes is awful. The machine in question is a 4¼ h.p. single, fitted with a Sturmey-Archer three-speed countershaft gear, and I always ride solo. The noise of the exhaust and tappets is simply deafening. Leading from the cylinder to the silencer is a pipe 1½in. outside diameter, and the outlet pipe from the silencer is 2ft. 4in. long × 1⅞in. ontside diameter; the silencer itself measures 2¾in. diameter × 7½in. (1.) How can I improve the silencer? (2.) Is there any means of getting the tappets to work more quietly? (3.) By fitting Druid spring forks instead of present standard forks, could I get less vibration on handle-bars?—R.H.McL.

(1.) What you want is a very much larger expansion chamber, and you might also try flattening the end of the final exit pipe through which the exhaust gases enter into the open air. (2.) We do not think you can do anything to the tappets beyond adjusting them carefully. (3.) It depends upon the cause of the vibration. If this is due to the road the fitting of different forks might make a difference, but if it is due to the engine then the new forks will convey the vibration to your hands in just the same manner.

The Use of Petrol Substitutes.

(1.) Will the use of petrol substitutes be allowed after March this year, if one's petrol licence has expired, or will motor cycling, except on national work, be prohibited? (2.) Would it be safe to use a vaporiser with petrol substitute mixture?—L.C.S.

(1.) There is no reason to suppose that there will be any ban at the present time on petrol substitutes. (2.) You should certainly use a vaporiser with a petrol substitute, or fit a warming device, which could be employed with petrol or any fuel, as it is always beneficial.

Remagnetising.

Would you kindly tell me the way to magnetise my magneto from a dynamo? The magneto has become weak. I cannot send it away, as I have to use the cycle practically every day. The magneto is of the Bosch type fitted to a Douglas engine?—H.B.

It is practically impossible for an amateur to remagnetise magnets satisfactorily; it is a task for an expert. To make a satisfactory job of remagnetising the magnets have first to be treated by a heat process to remove all magnetism. They are then rehardened and magnetised by placing them in contact with the poles of an electro magnet. The current is switched on and off several times for the necessary period to effect the remagnetisation. Are you sure the trouble with your magneto is weak magnets and not faulty contacts somewhere, owing to dirt or oil? When the magneto is detached from the engine the armature should jump round with a perceptible snap as it is turned over the maximum point. If it does so, and a reasonable amount of resistance is felt when turning the armature, it is evident the fault is not due to weak magnets. You should then go over all other points carefully, see that the high-tension carbon brushes are in good order and quite clean and free from oil, attend also to the contact breaker, see that the points are clean and not pitted and are breaking equally for both cylinders; the gap should be .4 mm., and make sure the rocker arm is absolutely free in its bearing. If the magneto has not been overhauled for some time it would be as well to remove the armature and see that the whole machine is quite clean inside; sometimes dust or foreign matter bridging the gap between the armature and the fields will have much the same effect as weak magnets. The magnets becoming demagnetised is a very rare occurrence indeed. Directly the armature is removed from the magnets place a piece of iron, such as a large spanner, between the magnet fields to act as a keeper. This is very important, especially if the armature is removed for any length of time.

DELAYS IN POSTAL DELIVERIES.

In view of depleted staffs, the curtailment of railway services, and the consequent delay in delivery of mails, readers will greatly assist by forwarding communications (including advertisements) as much as possible in advance of the dates of the issues for which they are intended.

Inlet Valve Lift.

(1.) What is the correct opening for an automatic inlet valve on a 3½ h.p. engine? (2.) Which would have the greater braking effect going down a hill at 15 m.p.h., lifting the exhaust valve or closing the throttle?—E.W.

(1.) About $\frac{3}{32}$nds of an inch. (2.) Lifting the exhaust. Of course, closing the throttle merely creates a vacuum in the engine, and there is no retarding effect, and the compression when the throttle is open acts merely as a cushion.

Failure to Start.

I have a 1911 2¾ h.p. twin, just overhauled, including the magneto, and it seems to be in good order, but I cannot get it to start. If I run with it for some time, it will fire six or seven times and then stop, and it only fires in one cylinder. It is getting plenty of petrol; when I open the throttle pure petrol runs out of the exhaust pipe. I have checked the timing, and found it all correct. I have also tried different makes of plugs, but found no difference, and when I put the plugs on top of the cylinders they seem to spark all right. I have also tried the throttle and air in all positions, but with no effect, and have packed all air leaks.—NOVICE.

Evidently the magneto is in good order. The difficulty in starting may be due to your having obtained some bad petrol (of which there is plenty about at the present time), or to the automatic inlet valves sticking. We should advise you to take these out and examine them carefully, see that both valves have about the same lift, and that the springs are reasonably strong, also that the valves are working freely.

Noisy Timing Wheels.

I have had the engine of my 3½ h.p. motor cycle down completely, and since refitting it gives forth a weird noise like the humming of a turbine or dynamo. This can be heard when turning by hand; it is very pronounced when slowing down after running on the stand. I have not run on the road since. When refitting, everything went quite freely into place, and no force was used. The flywheels were not dismantled. The crank case is well charged with oil. I certainly do not want the bother of taking it down again if you could suggest what is wrong, and assure me that it is unimportant. The engine seems quite as free as usual, and has a lively, healthy bark. The engine is a 1914 one, and has never had anything wrong with it.—F.M.T.

The noise may be due to want of oil in the timing gear case, or to the wheels being too closely in mesh for some reason or other. Without actually seeing the engine and hearing the noise it is a little hard to give a definite opinion.

Timing a Four-cylinder.

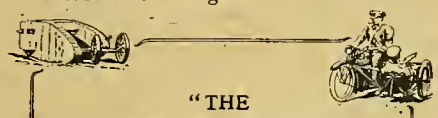
(1.) Would you please tell me the best way to time my four-cylinder F.N. motor cycle as regards the firing and exhaust valves? The engine is the old type, and fitted with a B. and B. single jet carburetter. I have had the magneto remagnetised and the engine overhauled, but it will only go for three minutes and then stop; it seems only to be firing in two cylinders. (2.) Would the carburation have anything to do with the engine stopping?—G.R.R.

(1.) The exhaust valves should be timed as follow: Set the exhaust valve to close just after the completion of the exhaust stroke. It will then commence to open when the piston is about one-seventh of the length of the stroke from the bottom of the firing stroke. The ignition should be timed as follows: Turn the crankshaft until the piston of the *back* cylinder is five to six millimetres from the top of the compression stroke. Unless the slide holding on the crankshaft has been altered, the carbon brush will point to the position of the bottom right-hand terminal of the distributer, assuming the latter is in position. Now grasp the contact breaker of the magneto, and turn it until maximum resistance is felt, and slide the magneto gear wheel into engagement with the corresponding wheel on the crankshaft of the engine. Having bolted up the magneto and fitted on the distributer, verify the timing. The points of the contact breaker should commence to separate when the back cylinder piston is in the aforementioned position. The wiring of the distributer in relation to the respective cylinders is: Bottom right wire to back cylinder; top right wire to third cylinder from back; bottom left wire to second cylinder from back; top left wire to front cylinder. The lengths of the wires will of themselves show to which cylinders they go. (2.) The carburetter may quite well be at fault. If there is a serious air leak at the induction pipe unions or at the carburetter union itself, and you had to inject petrol to start, the engine might run on the injection for a few seconds and then stop, as there would not be sufficient suction on the jet. The adjustment of the carburetter has a great deal to do with the starting of an engine. To start easily you should give a small quantity of rather strong mixture.

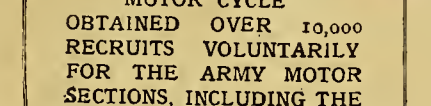
No Wonder!

I have a 1915 American magneto which I intended fitting to my machine, and when I had fixed it to the platform and turned the wheel there was a current through the machine with a fat spark at the plug. I then disconnected it from the machine and put it and the plug on wood. I then turned the wheel and found a poor spark at the plug. Could you tell me where I should be likely to find the leak?—E.H.

We do not think you will be likely to find a leak anywhere, as from your letter there does not appear to be any fault in the machine. It is rather curious that you get a spark at all if you lay the plug on wood, as wood is practically an insulator, or, at any rate, a very bad conductor of electricity, and it is through the wood that the return current had to pass to the base of the magneto.



"THE MOTOR CYCLE" OBTAINED OVER 10,000 RECRUITS VOLUNTARILY FOR THE ARMY MOTOR SECTIONS, INCLUDING THE FAMOUS TANKS. A LETTER OF APPRECIATION WAS SUBSEQUENTLY RECEIVED FROM THE ARMY COUNCIL.



Difficult Starting.

As I have just purchased a twin Moto-Rêve which is giving me considerable trouble, I should be very grateful if you would assist me. The machine is fitted with a B. and B. carburetter, and I get the following results from it when machine is on the stand: Unable to start engine when cold unless I warm carburetter and pedal hard. When engine is warm I can start by a push down on pedal and get fierce acceleration, but cannot throttle down below a road speed of twelve miles per hour without engine stopping. Wet petrol is blown from carburetter when engine runs fast on stand. On the road I am unable to start engine either by running or pedalling, although, as I say, one push will start engine if put on stand. Through reading your paper I have made sure of the following before writing you. That the exhaust valve closes at top dead centre. That it opens before the completion of the working stroke. That the platinum points break six millimetres before the end of the compression stroke. That when tested with oil no leaks show round the induction pipe, inlet, or exhaust valves. That there is a spark at each plug. That there is good compression in both cylinders. That variation in valve and ignition timing and alteration in size of carburetter jet does not improve the running. I am in doubt about the inlet valves (automatic). How can I tell if the springs are too strong or too weak? and how much opening should be allowed the valves?—C.W.S.

It is a little difficult to account for the trouble which you are experiencing, unless it is the bad petrol which one gets nowadays. The fact that wet petrol is blown from the carburetter seems to indicate that the inlet valve springs are too weak. We note that you have checked over the timing of the valves and ignition. Of course, the whole trouble may be due to the automatic inlet valves, which are sticking and sluggish when the engine is cold, and they also prevent slow running. You must have a mechanical valve to get slow running unless you so set the automatic valve that the springs are too weak for fast running. Automatic valves should open on a pressure of about five ounces being applied to the stem. This will give you an idea of the strength of spring required. The valves should open about $\frac{3}{32}$in.

READER'S REPLY.

Uneven Firing.

As a rider of an Enfield two-stroke, I should suggest that "W.P.S.," on page 199, March 1st, try a Sphinx B41 plug. I have found that this plug gives the best running for my two-stroke.—G. R. RISSEN.

RECOMMENDED ROUTES.

WOLVERHAMPTON TO MERTHYR TYDVIL.—R.E.J.

Wolverhampton, Kidderminster, Bewdley, Tenbury, Leominster, Willersey, Three Cock Junction, Brecon, Merthyr Tydvil.

LIVERPOOL TO ASPATRIA (CUMBERLAND).—H.T.

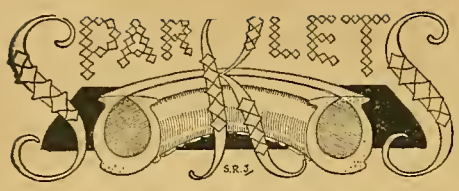
Liverpool, Ormskirk, Preston, Lancaster, Carnforth, Kendal, Windermere, Ambleside, Grasmere, Thirlmere, Keswick, Bothel, Aspatria.

NEWCASTLE-ON-TYNE TO OCKLEY (SURREY).—W.L.

Newcastle, Durham, Darlington, Northallerton, Boroughbridge, Wetherby, Ferrybridge, Doncaster, Retford, Newark, Grantham, Stamford, Stilton, Eaton Socon, Biggleswade, Hitchin, St. Albans, Elstree, Harrow, Sudbury, Hanwell, Brentford, Richmond, Kingston, Leatherhead, Dorking, Ockley. Approximately 365 miles.

GOSPORT TO MALTON, VIA SLOUGH.—C.E.H.V.

Gosport, Fareham, Wickham, Corhampton, Hedge Corner, Chawton, Alton. Farnham, Farnborough, Bagshot, Ascot, Eton, Slough, Denham, Rickmansworth, Watford, St. Albans, Hatfield, Welwyn, Stevenage, Baldock, Biggleswade, Eaton Socon, Alconbury Hill, Norman Cross, Wansford, Stamford, Grantham, Newark, Tuxford, Retford, Bawtry, Doncaster, Ferrybridge, Brotherton, Sherburn, Tadcaster, York, New Malton.



The Zephyr Motor Unit.

We are informed that the actual weight of the Zephyr motor unit, referred to in our issue of February 22nd, is 30 lb., and when the outfit is manufactured the weight will be reduced to 28 lb. by the employment of lighter metals.

Government Test of the Phillips Magneto.

Messrs. Phillips Magnetos, Ltd., Birchett Road, Aldershot, whose magneto we described in *The Motor Cycle* of November 2nd, 1916, inform us that this instrument was recently tested by a Government Department, which has notified the company that the magneto proved to be satisfactory in every way.

Petrol Substitutes.

We are informed that Messrs. A. W. Gamage, Ltd., Holborn, London, E.C., now keep a stock of petrol substitute in two-gallon tins. Delivery is uncertain owing to railway and transport difficulties, but motor cyclists can always get supplies by calling at Messrs. Gamage's Holborn depot.

Up to the present these substitutes do not come under the Petrol Committee's control.

The firm stocks two kinds of substitute — one closely allied to paraffin and the other similar to benzole.

Economy of the 3 h.p. Enfield.

The excellent consumption figures of the 3 h.p. Enfield have frequently been referred to in our pages. For instance, "Auriga" covered 520 miles (including the crossing of Dartmoor, which neccssitated much low gear work) on four gallons. Another member of our staff rode to Bristol and back (200 miles) on two gallons over winter roads. We now hear that 236 miles have been ridden over New Zealand roads on just under two gallons by Mr. W. G. Stenhouse, who says that the 3 h.p. Enfield is an ideal solo machine for use in the Colonies, where a machine has to stand up to some very rough and muddy roads.

Review.

"Electricity and the Motor Car" (second edition, revised). F. H. Hutton. Iliffe and Sons, Ltd., 20, Tudor Street, London, E.C. 2s. 6d. This useful publication has recently been revised and improved. While it appeals more especially to the owners of motor cars, the book is likely to be of great value to anyone using a motor vehicle of any type propelled by an internal combustion engine, as it deals with the electrical side in a most efficient and thorough manner. It is fairly safe to assume that most motor cyclists are potential motor car owners, and it cannot be otherwise than beneficial for a motor cyclist to read such an interesting subject as electricity as applied to motor cars. Not only is the subject dealt with from the lighting and starting point of view, but the question of ignition is also treated in a very efficient manner.

Petrol Pills.

The makers of the preparation known as Glitter Glass, which is used on screens when driving in the rain, now market petrol pills. These are simply dissolved in the spirit, and are recommended by the Atkinson Manufacturing Co., Ltd., Guildhall Street, Preston, as a means by which to eke out the petrol supplies.

Record Hub Gear Repairs.

The County Cycle and Engineering Co., 64, Staines Road, Hounslow, inform us of a record repair to a hub gear which they carried out recently. The gear was brought into their premises at 9.30, completely dismantled, all parts were shown to the customer, and those requiring replacing were pointed out. At ten o'clock, half an hour later, the wheel was delivered, and the customer found that the gear was in perfect condition. The company send us a letter from the customer confirming the facts we have just recorded.

Catalogues Received.

We are in receipt of a catalogue from Messrs. Cravens' Patent, Ltd., 97, Corporation Street, Manchester. In it we notice a selection of luncheon baskets, of a type highly suitable for drivers of sidecar combinations.

We have received a booklet describing the new Model H Matchless, that attractive 1917 model flat twin, details of which were given in *The Motor Cycle* of 16th November, 1916. The reading matter is, of course, intensely interesting, and the illustrations first-class.

"Case-hardening," a booklet referring to the D.B.S. carburiser, manufactured by Messrs. David Brown and Sons (Huddersfield), Ltd., Park Works, Lockwood, Huddersfield. Messrs. David Brown and Sons are closely connected with the manufacture of parts for all types of motor vehicles, and in the manufacture of these case-hardening is, of course, one of the most essential points requiring attention.

"Motor Cycles and How to Manage Them."

Recognised everywhere as the standard handbook on the motor cycle, its care and management. Every motor cyclist, whether beginner or experienced rider, will find the book extremely useful.

Price 1/6 net. By post, 1/10.

"Hints and Tips for Motor Cyclists."

This book gives hundreds of useful "wrinkles" and items of information concerning the running, management, and repair of motor cycles, and contains what may be termed the cream of up-to-date motor cycling knowledge. Altogether nearly 1,000 hints and tips are given.

Price 1/- net. By post, 1/2.

"Tracing Troubles."

Motor Cycle Faults, Their Identification and Their Remedies Fully Explained.

The object of this book is to enable motor cyclists not only quickly to trace the cause of any fault in the machine, but to remedy the trouble in the shortest possible time. The system is applicable to all makes of machines, both four-stroke and two-stroke.

Price 1/- net. By post, 1/2.

Obtainable through leading booksellers, or direct from the publishing offices of "The Motor Cycle," 20, Tudor Street, London, E.C., England.

A Good Substitute.

During the petrol shortage in the summer time, our attention was called to Petrolior, made by Messrs. Archibald Vickers, Ltd., 28, King Street, Covent Garden, London, W.C. Two members of our staff used this fuel with excellent results, one in a Matchless-M.A.G. engine and the other in a 4 h.p. Douglas. In neither case was any additional device employed, both carburetters being fitted with a warm air intake, but the Petrolior gave excellent results, only demanding that the spark lever should be judiciously adjusted from time to time when any sign of knocking occurred.

Petrolior is a hydro-carbon distillate containing neither paraffin nor petrol, of water-white appearance, and giving off a faint petrol-like odour. The flash point is 76-80°, and the specific gravity between .771 and .779. When evaporated there is practically no residue, the amount being less than .005.

AVERAGE PRICES.

WE give below the prices of second-hand machines offered for sale in the last issue of *The Motor Cycle*. Difficulty in obtaining a sufficient number of one model often arises, owing to the fact that many advertisers omit some of the essential details, while others include fitments not supplied with the standard machine.

HELPING TO WIN
is what the

STURMEY ARCHER
COUNTERSHAFT GEAR

is doing to-day.

And after the war is over it will still be "helping to win" — the best results from every motor cycle.

Make a note of it.

Sturmey - Archer Gears, Ltd., Nottingham.

I SUBMIT there

is a solid reason why you should adopt a

BINKS CARBURETTER, viz.:
YOU CUT YOUR FUEL BILL IN TWO

if you adopt my system and use my fuel. You can, of course, use petrol or benzol without alteration.

Price of Carburetter complete—

49/-

plus 10% extra war cost.

Fit any Machine.

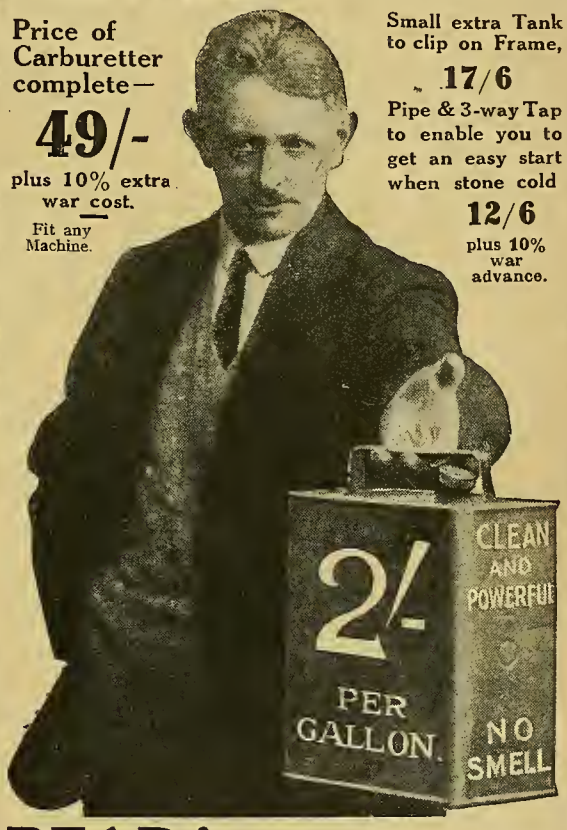
Small extra Tank to clip on Frame,

17/6

Pipe & 3-way Tap to enable you to get an easy start when stone cold

12/6

plus 10% war advance.



READ!

MY 3-PHASE JET DAMPING CARBURETTERS

have such perfect vaporising properties that they enable you to use fuel at **2/-** per gallon in 42-gallon casks, which you are allowed to keep on your premises. Casks **12/6** extra, returnable at **10/-** each, less ½d. per gallon rebate to users of the "Binks" Carburetters purchased within the last two years. Your engine will tick over dead slow, and pull dead slow in traffic, yet give the full power. It is almost impossible to tell you are not running on petrol at **3/-** a gallon. It cannot damage your engine or soot it up, and makes Motor Cycling possible in these times.

I give you my personal assurance of the truth of what is stated above. Please send at once for full particulars of the carburetter, and also for my Treatise on Carburation, and terms of One Month's Approval Trial.

Owners in London invited to apply to Messrs. Oylers, Ltd., of 35, New Cavendish Street, who have facilities for supplying and fitting these carburetters.

C. BINKS, Ltd., Eccles.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., & Co. and crossed

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed, "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

Abingdon.

ABINGDON, 3½h.p., 1914, Grade Multi pulley; £25. —18, Beechwood Av., Thornton Heath. [X7411

ABINGDON King Dick, 3½h.p., N.S.U., F.E., Phœnix sidecar; £35; trial.—R., 304, Hanworth Rd., Hounslow. [9161

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

Substitutes by Permit.

PETROL substitutes and the best way to use them have been very much to the fore of late, and for a variety of reasons. These substitutes are for the most part slightly cheaper than petrol; some riders find that, with suitable means of vaporising, they give results which compare well with those obtained from the lighter fuel; the mileage per gallon should be slightly better, and, lastly, many riders required a larger allowance of fuel than their petrol cards gave them.

Since the notice issued by the Petrol Control Committee on March 10th, the last reason no longer holds good, for the substitute has to be entered on the purchaser's card in the same way as petrol—and presumably it will, therefore, be subject to the tax of 6d. a gallon paid by the rider to obtain his card, if not to the former petrol tax which is included in the price. This notice is, of course, issued because it is just as difficult to import substitutes as petrol, and the tonnage required will in each case be the same, but there must be large stocks of substitutes ready in the country, and it is desirable that these should be used to the best advantage.

Users' experiences have been chronicled in these columns for months past and valuable advice proffered by readers, supported by expert writers, as to desirable forms of vaporisers, and these will prove valuable for reference. But, as a leading agent (Mr. F. S. Whitworth) points out in a communication appearing on another page, what is wanted is a committee of practical men, including manufacturers, to co-ordinate these amateur efforts, and by test and collaboration decide upon the most suitable form of vaporiser for specific makes of motor cycles. Doubtless were the conditions more propitious such a committee could readily be formed, but as it is we fear the question must be deferred until after the war.

It may be well here to remark that the majority of different designs of vaporisers reviewed in *The Motor Cycle* have been actually tested on the road in conjunction with heavy fuels; in other words, they are not paper designs based upon mere assumption.

Eliminating Weaknesses.

IN a recent issue we made some remarks on the subject of the design of military model motor cycles, particularly concerning the recurring troubles on designs which existed prior to the outbreak of war. Our main point was that these weaknesses could well be eliminated at the root under a proper scheme, and thus the workshops at the different battle-field bases would be less occupied with unnecessary repair work and the men obviously left free for other more pressing needs. Since our notes were published other information has reached us which shows that our remarks were timely. The point now emphasised is the question of the supply of spare parts. One manufacturer has said that his output is actually restricted by reason of the large quantity of spares demanded with every complete unit, the quantity of spares having been laid down from the first and not having been altered. Concerning our previous remarks, it has been pointed out to us that the military authorities refuse to accept certain modifications in design as recommended by the actual manufacturers, for the very good reason that the spare parts difficulty—a very big question when one considers the number of transport bases scattered almost the world over—would become extremely complicated. Evidently then the disease is preferred to the cure for the reasons stated. But that is not a complete answer to our points; we instanced several which do not involve the question of spares. Take one or two only: the most desirable shape of handle-bars, the best position for the footrests to provide the utmost security on treacherous surfaces, and the almost universal demand for handle-bar-controlled clutches.

An index to the advertisements in this issue will be found on the page facing the back cover.

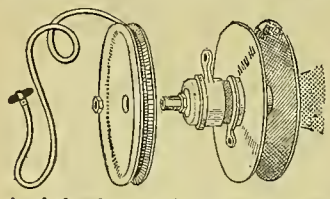
IDEAS: Useful and Ingenious.

A HAND STARTER.

IN a recent issue a correspondent invited suggestions for fixing a starting device to an early model Zenith. It seems, therefore, that the following description of the device as fitted to a reader's Zenith may be of interest to him, and possibly to riders of other machines.

A simple hand starter was made by fixing a pulley on the engine-shaft, actuated by a leather strap as shown in the sketch. A flat was filed on the shaft to take a corresponding flat on the hole in the pulley, and then bolted up tightly by means of the lock nut provided. A five to six inch pulley will be found to give ample purchase, whilst four or five laps of strap give the necessary revolutions for starting.

The end of the strap must not be anchored to the pulley, but merely slipped into a hole drilled in the groove



A simple hand starter for a Zenith actuated by a leather strap.

for that purpose. If a liberal injection be given to free the pistons a sharp pull up on the strap will start the engine with ease.

A PILOT JET.

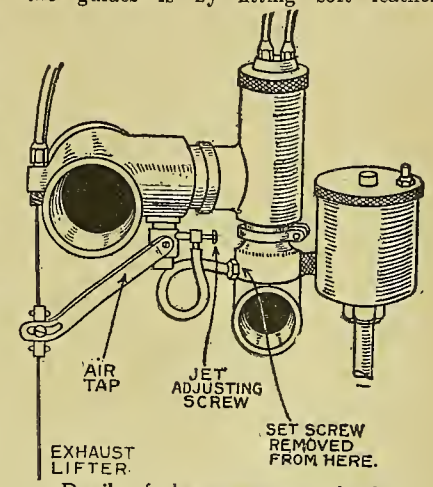
A PILOT jet was made from an ordinary gas by-pass with adjustable aperture. This was fitted into the underside of the induction pipe in such a position as to enable the tap lever to be fixed to the Bowden exhaust lifter wire. The screw which seals the end of the petrol feed channel connecting the float chamber and jet, as fitted to old type B. and B. carburetters, was removed and a small feed pipe connected from this point to the by-pass jet (see sketch).

By adjusting the air lever on the Bowden wire the correct mixture can be obtained for slow running under all conditions. The air supply being operated by the exhaust lifter, cool air is drawn into the cylinders when coasting down hills, etc., thus effectively cooling the engine.

TO ELIMINATE AIR LEAKS

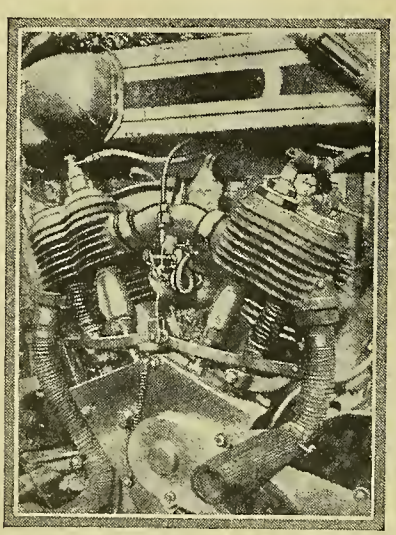
WORN valve guides are invariably the cause of difficult starting and erratic running at slow speeds. Great difficulty is experienced at the present time in obtaining such parts, so in consequence one has to be content with makeshift replacements until the manufacturers can again supply them.

A means of eliminating air leaks at the guides is by fitting soft leather



Details of the arrangement whereby a pilot jet was fitted to a standard B. and B. carburetter.

sheaths over the spring and tappet, as in the case of the J.A.P. engine illustrated. These may be made from pieces of old leather gloves placed loosely round the spring, the seam being doubled and stitched closely, the ends being fastened with copper wire.



Leather sheaths fitted over the inlet spring and tappet to eliminate air leaks. Beneath the induction pipe is the pilot jet made from an ordinary gas by-pass.

ECONOMICAL FLOODING.
